THE TEACHING OF THERAPEUTICS*

RAY LYMAN WILBUR, M.D.
SAN FRANCISCO

To heal has ever been the function of the physician. Therapeutics is so much older than pathology that it *is but natural that the latter should have had difficulty* in having its tenets promptly and fully recognized in the treatment of disease. Empirical principles die hard, for they have developed by that long trial and struggle —that "survival of the fittest"—that speaks for permanency. *The relief of pain by heat was ages old before* the seat of pain was located in the nervous system. To the man with the pain the attendant with the hot *stone has always been preferable and always will be* to the man who is content with a knowledge of the *cause of pain, its probable duration and its significance* from a pathologic point of view. It is but natural that *the man with the knowledge should show contempt for* the man with the hot stone, and more natural still that the sufferer should sympathize with the one who brings *speediest relief. Thus, with the growth* of medical science, therapeutics has suffered from neglect on the *one hand and overemphasis on the other.* The development of schools of medicine with their various methods of treatment has been a blight on medical growth, both scientifically and sociologically. The last twenty years has done much to give us a practical and in some instances a specific therapeusis for many conditions, and it is clear that the day of schools is passing. Even *those schools* of therapeutics that are practically a religion to their adherents are showing signs of disintegration. *The sin of nihilism toward drugs* in the name of science delayed but will not prevent the early *coming of the day of rational therapeutics based on* sound investigation, careful observation, critical selection and general principles broad enough to incorporate the essential and the useful of all forms of healing.

The present teaching of therapeutics is in an unsatisfactory condition. *The dead hand of the past has* nowhere else in medicine thrown its heavy shadow so far across the path *of progress and growth. The old* prejudices are among us, both within and without the medical profession. We must free our minds from passion, bias, the spirit of controversy and seek for the truth and seek to teach it. We must welcome and adopt all that is worth while in the various schools and make it a part of medical science. It is possible now to extract the kernel of truth from most *systems of healing.* We must do so or we *delay the hour when medicine is to take fully her noble place in the everyday* life of all living men and women.

The prime essentials of all therapeusis are two: first knowledge of the conditions treated and their usua course; and, second, a sympathetic desire to give relie and a knowledge of how to do so. The physicians— and there are many of them—whose minds stop working when a diagnosis is made are the best friends o the cult and the quack. The only way to teach therapeutics is to practice it under the eye of the student Can anything *be more deadening and disheartening to* the student than to take notes from the enumeration in a prosaic lecture of the various drugs "good for certain complaints," with their various doses? The absurdity of such teaching is now becoming generally recognized. In some institutions the historical element which is such a strong factor in hampering our medical schools, still separates medicine and surgery from *therapeutics. They must all go together* and grow together. With increasing scientific thoroughness treatment will forge again to the front in the art of the physician.

Pharmacology has gained a firm hold in medical instruction. It must not fail to extend its domain to *the bedside, to become a part of the life* of each and *every teaching clinic.* It must be taught so that dog experiments will be seen from the viewpoint of man rather than that drug effects on man shall be looked at primarily from the standpoint of the dog. Just as the clinical observer is again beginning to have his day in scientific medicine, so the value of bedside pharmacology is being increasingly recognized. Practically, it may be said *that the modern teaching of therapeutics* should concern itself with a choice from that great *hodge-podge, known as the Materia Medica,* of the useful and the usable; with a study of practical pharmacology, *based on physiology; with bedside instruction in pharmacology* and therapeutics as a distinct part of medicine and surgery; *and with the adoption and adaptation* of all that is worth while in the various systems of medicine. The physiologic effects of *hyperemia are much alike whether induced* by a diffusible stimulant, a mustard pack, a hot bath or general massage. We should teach the student *the significance of the hyperemia* and show him the various methods by which it may be induced. He should understand that the osteopath, the masseur, the hydrotherapeutist, all may obtain therapeutic results even if their knowledge is crude, their logic poor, their theory unscientific. They may *lack that first* prime requisite, knowledge of disease process and power of diagnosis, but they make up for it in *the minds of the ill* by *their* assiduity in *that* second essential, the sympathetic desire to be helpful and the willingness to work for results. We must cultivate this latter in our coldly analytical laboratory students, when they reach the clinic; or, as physicians, they will find that their superior knowledge is not a sufficient magnet to draw patients to them from the hands of the drugless healer and the faddist.

---

* Chairman's address before the Section on Pharmacology and Therapeutics of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

Drugless healing is a reproach to medicine. It should never have come into being as an entity. We should not be so associated with bottles and evil doses that the prescription is recognized generally as the badge of our profession. The teacher of therapeutics should be the teacher of medicine and of surgery, and as such he should demonstrate to the student something of the scope of the possibilities in the relief of the sick. Bier's hyperemia, the use of oiled silk in dressings, the after-care of a patient who has been operated on; the intelligent use of the ice-bag should be taught by the surgeon just as the use of the mustard-plaster, the cold sponge-bath, the administration of digitalis and of calomel should come from the teacher of medicine.

When physical therapeutics is taught by clinicians from the sound basis of physiology and pathology in all of our medical schools, the problem of drugless healing as it is practiced outside of the profession will no longer exist. The teacher must remember that a cannon-ball rolled over the outside of the abdomen is more satisfactory to many constipated patients than a cathartic pill inside, and that a dietary cure is even more gratefully received. Skill in the use of drugs and other forms of treatment can only come from careful observation. One physician succeeds where another fails, and often with the same remedy or the same method. We all know the splendid effects of calomel on the patient who announces that he cannot take it, because Dr. S. has tried it either without success or with subsequent evil results. A few good drugs, well understood, are of more value than a whole medicine-chest. The man who has been taught the intelligent use of such remedies as opium, quinin, castor oil, calomel, the salicylates and digitalis need not fear as a competitor the drug-clerk who later studies medicine and who has everything on the shelves at his fingers' ends.

Day-to-day instruction in the use of drugs and in their careful selection is required of the clinical teacher. A few minutes in each bedside or outpatient clinical conference will bring out the main points. This is vital, since the majority of the text-books on therapeutics are merely well-arranged cemeteries filled with records of treatments that have gone before. They attempt to list most of the drugs that have been used for any given condition and are apparently satisfied with the mention of any form of treatment if they can put the responsibility on some one else. Selection is just beginning to be recognized as the main function of the author of such a text-book. If he cannot intelligently choose the wheat from the chaff, how is the young physician who looks to the book for guidance to be able to do so? The student should be taught to determine the leading symptoms demanding treatment and to care for them promptly, provided they are not needed as guides in diagnosis. Along with this should go a thorough instruction in the effects of each drug given and in its possible action on various bodily functions and the method of the correction of these, if necessary. Physicians and laity alike are too prone to consider subsequent disease symptoms as due to drugs previously administered. Pharmacologic bedside studies alone will give the proper judgment in the interpretation of such conditions.

We must also recognize that elegance in pharmacy has its place in therapeutics. The modern stomach cannot be ignored. The psychic element in gastric function holds for drugs as it does for foods. And we must not lose sight of mental therapeutics. Milk-sugar mixed with hope and encouragement is sweeter than saccharin to many a sufferer. Reassurance is often as comforting as opium and has fewer after-effects.

My plea, then, is for a broader and for a narrower point of view in the teaching of therapeutics; a broader one to include all that is essentially sound or that can be scientifically tested regardless of origin or school, and a narrower one to exclude all that is outgrown, that savors of polypharmacy and that smacks of the quack. It is further for pharmacologic instruction of the student with the dispensary patient before him, or at the bedside and for a firm union of the teaching of therapeutics with all forms of clinical instruction.

Sacramento and Webster Streets.

THE FUTURE OF THE MEDICAL MAN*

JOHN GEORGE ADAMI, M.D.
Professor of Pathology and Bacteriology, McGill University Medical Faculty
MONTREAL

Gentlemen of the Graduating Class:

Need I tell you how I appreciate the honor that has been conferred on me by your dean and the medical faculty of Rush Medical College by asking me to address you this afternoon at this, the culminating moment of your university career? But let me confess to you that with the honor comes the sense of heavy responsibility. From him to whom much is given much is also asked. Time and again in the years that are to come, this graduation ceremony will recall itself to the minds of each one of you as marking an epoch. It would be well could I utter words which should impress themselves in such a way that they remain with you as part and parcel of the event, words memorable for themselves as well as of the occasion; but if the utterance of such words is given to few, very few, of us, it is proper that what I say should be not unworthy, that it should attune itself to the occasion. It would be out of harmony with the event were I to seize this opportunity to deliver my message as a pathologist, and enunciate my views concerning some moot point in medical science; were I to read you a lecture on advanced pathology.

I must perforce strive to utter thus that which will appeal to each of you, that which will be helpful. During the last few years you have been satiated with lectures on special topics; to-day it is for me to strive to sum up the significance of all this teaching—all this education—in one comprehensive address. For four years—aye, and for long years previously—you have been preparing to enter the practice of medicine; to-day you are at the very entrance of that practice, at the threshold; to-day the university gives you its testamur. Each one of you must be asking, "What of the future?" Now, I am far from wishing to inflict a sermon on you, but at this particular moment I do but reecho the thought that is uppermost in all your minds. All the work of all these years has led to this moment, and now what next? What about the years that are to come?

---

* Commencement address at Rush Medical College, Chicago, June 12, 1913.

NATURE OF TRUE KNOWLEDGE

Well, gentlemen, I trust that I shall not shock you too much when I lay down that you know next to nothing; you are but at the beginning of knowledge. I say this knowing perfectly well that there is no period in the whole of a man's existence when he feels so replete, so distended, with medicine as immediately following on the final examination and graduation. I speak knowingly, for I have been there myself. But, gentlemen, this sensation is comparable to that of the woman who, suffering from flatus, imagines herself to be in the latter months of pregnancy. It is an equally false conception. In the first place, in a four-year course, however well conducted, your teachers can have given you but the basal outlines of their respective subjects. We know how small a portion of one subject we can instil into you in the brief months during which you sit under each one of us. That is the reason why we are constantly striving to lengthen our courses—why each year you are made to feel more and more the heavy burden of the training. The better the teacher, the more, I think, his conscience pricks him for the inevitable deficiencies of his curriculum; and, paradoxically, I may add, the simpler and more elementary he makes his teaching, realizing that, as his subject cannot possibly be covered, his time is best employed in laying down secure foundations on which later the student may build a fair and seemly superstructure.

In the second place, true knowledge consists not in cognition, in the possession of a store of facts, but in the capacity to utilize them. You may be chock full of medical data, but until you have learned to employ these data, until you have tested their value in practice, you are but, as it were, sucklings in medicine. Heaven preserve the patients of the man who passes straight from graduation into private practice! Great as is the *vis medicatrix naturae,* that imposes all too heavy a strain on it. This only would I say, that the vast increase in the practical work of the course that has been brought about during the last generation should make the student more secure of his data, more capable of using them with advantage; but notwithstanding the increased contact with the actual patient during the last two years of the course, which in comparison with your predecessors you have been afforded, I still doubt whether to-day the student on graduation is as capable of launching out into the world, is as serviceable to his patient, as was the product of the days of apprenticeship forty years ago. When it comes to a matter of differential diagnosis, he may be vastly his superior; but in knowledge of treatment of the patient as distinct from his disease, he is as vastly inferior. Wherefore, I trust that one and all of you before me have dedicated yourselves to at least a year of hospital internship, that you may learn the art as distinguished from the science of medicine.

That learned old physician, John Caius, physician in succession to Edward VI, Mary and Elizabeth (at whom, indeed, Shakespeare seems to have poked fun), when he refounded the college which bears his name in Cambridge, with that love of symbolism not uncommon in his generation, built three gates. The gate of entrance with its little wicket (now significantly removed as a relic into a back garden) he called the Gate of Humility. In the midspace of the college, supported on either side by the students' rooms and college buildings proper (which on their foundation stone were dedicated to Knowledge) was and still is a wide and lofty archway, of almost Roman simplicity and severity, with the inscription "Virtutis"—the Gate of Virtue (and of Wisdom). At the farther end, leading out to the public schools, where the university confers its degrees, is the exquisite and richly ornamented Gate of Honor, about the earliest example of Italian Renaissance architecture to be found in England. All of which is a parable. I for long wondered why Caius when he made this gate so beautiful made it so diminutive. On first thought, one would expect something of goodly size, suggesting a triumphal arch. But no, the passage through it is narrower and lower than that through the old gate of entrance; the Gate "Virtutis" would as it were swallow several of it. Did he not here intend another parable—that the man who completes his course with honor should pass out, out of the college into the wider world, even as he entered college, with becoming and even greater humility?

You are thus at the beginning of medical learning, not at its end; but if true medical knowledge and wisdom come with practice—if you as medical men are to be students all through the days of your active life—how are you to comport yourselves toward your profession?

MEDICINE AS A BUSINESS

Here on the borders of the West, I feel some delicacy in entering on this subject; but at the same time, for the love of my profession, I recognize the necessity that I should speak frankly and urgently. For what in the East we call "the Western spirit" has entered into medicine. I protest against this appellation: this spirit is neither Eastern nor Western; it affects the whole continent; it affects the modern world in general; it is the spirit of the age. We live in an age when a man's status is determined by his apparent wealth. That is inevitable with progressive democratization. Worth may make the man and the want of it the fellow. The more philosophic we are, the more freely we admit with the poet that all else is "leather and prunella"; but notwithstanding and nevertheless, save in the most outstanding cases, worth carries with it no social recognition—it is imponderable. Man—and woman—demands some standard of comparison, and if relative rank be largely abolished, there is nothing to fall back on but worldly possessions, whence it is that, whereas of old the physician, and his wife, had a status dependent on his profession—whereas he ranked next to the lawyer, and as a professional man took precedence of those engaged in commerce—to-day he who has scooped his millions from the manufacture of a quack remedy is accounted the greater, and takes without shame the upper seat; and almost perforce the physician is driven to strive after more than a mere modest competence, if he is to be of standing in the community.

Therefore the student entering medicine to-day is apt to have before him something not included in the hippocratic oath. Certain it is that an increasing proportion of medical men is more concerned over the means of improving its balance in the bank than over the means of improving the health of its patients, and regards social success as more to be considered than professional capacity. What is more, other influences are leading in the same direction. It is to the credit of the young manhood of this country and this generation that it realizes as never before its duty to make its own way in the world. To me there is something splendid in this impatience of the yoke of indebtedness, in the determination to repay at the earliest moment, whether to parent or family friend, the heavy cost of the medical course. Often, it is true, I am torn between admiration and regret. I see men who [illegible] convinced, [illegible] uld become leaders in the profession could they devote a year or two to advanced medicine and research, men who would thereby reap some fifty, some one hundredfold in the years that are to come, shortsightedly, as it seems to me, let slip the opportunity and consign themselves to mediocrity in their keen anxiety to be out of debt and independent. I think that in such cases my admiration predominates, but my regret is also poignant; but such men inevitably begin practice with the need to make a pecuniary success almost too prominently and constantly before them.

Then, again, it is but human to hold that there be a certain ratio between the amount of capital invested in any enterprise and the return yielded thereby. We may regard the time and money expended on his education by or on behalf of the medical student as the equivalent of capital invested. Within a generation—within little more than half a generation—this requisite capital has increased to an extraordinary extent. This fact was brought rudely before me within the last few days, when discussing with my old friend, the dean of the medical faculty of the University of Minnesota, Professor Wesbrook, the developments that have occurred in the seventeen years during which he has been connected with that school. In 1895, when he joined the faculty, all that was demanded of the student was a course of three years of seven months each; in all, twenty-one months' instruction. Soon that was raised to four years of nine months—thirty-six months—more than half as much again. To-day, before the degree is granted, the university and the state demand six years of nine months (two years in arts and four in medicine), and one full year of twelve months in a hospital approved by the university. The three years of 1895 have given place to seven years, the twenty-one months to sixty-six. The time capital has been more than trebled, and the same must be true of the pecuniary outlay; and when we compare the difference in the quality as well as in the quantity of education afforded, when we realize the quality of the output, is it to be wondered at that the physician of to-day should demand a higher return?

MEDICINE AS A PROFESSION

And yet, gentlemen, while admitting that there is an evident increase in the number of those medical men who regard their work as a business, the noble fact remains that to-day as in all ages the lure of medicine is such that the majority follow it from pure love of the work and of their fellows. The majority still devote themselves to it with the old spirit, caring little about the monetary return so long as they are secure of a decent competence; they regard it as what it is—a profession and not a trade. Their life work is to bring healing to the sick, to make the weak strong, to soothe the suffering, to help their kind. This to them is before all else. And here, in aiding poor humanity, the physician's work approaches the divine. It is at least suggestive that, as Dr. James Douglas has pointed out, of the twenty or twenty-two miracles recorded as being performed by the Founder of the Christian religion, no less than seventeen are acts of healing, of raising the sick, of restoring sight to the blind, of curing the palsied, of so-called casting out of devils, or restoring those apparently dead to life. It was through this power in healing the sick that Christ impressed his divinity on his generation. Whatever our faith or want of faith, this must strike us as most significant. "From the Most High cometh healing."

Indeed, this same spirit of devotion to the main object of our profession has been shown in our generation more than in any other period of the world's history. In every center of population throughout the world, we have presented groups of medical men giving their whole time and all their energies to the investigation and perfection of methods not of cure but of prevention of disease. We can proudly state that ours is the only profession which, were the making of money its prime object, with open eyes and set purpose indulges in the suicidal policy of endeavoring consistently to reduce its means of sustenance. Our leading thinkers, our leading investigators, have before them the banishment from among us of the vast array of infectious diseases, and in their efforts have the loyal support of the whole profession. Thus in the body corporate of medical men, as in the body of each individual being, there is this constant war between opposing motives.

EVOLUTION OF MEDICAL IDEALS

Perhaps I have not been sufficiently following the biologic literature of the last few years, and what I am about to say is already a commonplace; but after a study of mendelian heredity I have wondered why no one has come prominently forward to demonstrate the why and wherefore of progressive evolution and its inevitability in the terms of dominant and recessive. So far as I can see, in every mating it is the positive acquirement or quality that is dominant; the defect or absence of the same that is recessive. Thus hairiness is apt to be dominant to smoothness or want of hairs; the presence of eye pigment to absence of pigment; with the result that if there be mating between the possessor of a dominant quality and a possessor of a recessive quality the offspring of the first generation all present the dominant quality. There it is, although not absolutely fixed; the recessive character is also present but latent; and if two of this generation mate the chances are that the recessive quality will show itself, but only in the proportion of one to four. Three out of four will present the dominant, the added quality; in one of the three firmly fixed, in the other two with the recessive quality also present but latent. In this way, you see, the dominant quality, acting on the majority of individuals of the strain, gradually becomes predominant, and there is the greater likelihood that if some further positive feature be acquired this will fall to the lot of some member of the major class; and so as the ages progress the inevitable tendency is to a steady increment of properties—to, in short, progressive cumulative evolution.

So it is with all true progress: it is cumulative; it has to be. Two centuries ago, beyond certain crude ideas regarding disinfection, preventive medicine was almost non-existent. The function of the physician was only to cure. Then this added idea of prevention showed itself in some of the greater men of the profession and steadily with successive generations, being a positive acquirement, it is becoming more and more a fixed principle of the profession.

Whither is it leading us? To this, it seems to me: The time is on us when the physician must make his livelihood, not for the cure of the patient but for preserving him in health and preventing him from falling sick. There will always be with us what may be termed physiologic medicine, the caring for women in normal childbirth, for the very young and the very old; always traumatic medicine or surgery; always a certain not inconsiderable amount of family medicine—for Johnnie will indulge in green apples so long as there are Johnnies and apple-trees, and will suffer in consequence. Nay, more, I do not in the least imagine that we shall gain ascendancy over pathogenic bacteria as a body. I feel convinced that if we drive out such diseases as tuberculosis, typhoid and scarlet fever, we shall weaken the general bodily immunity. I think that we are realizing more and more that a man does not so much escape the ordinary infectious diseases because he has a strong inherited immunity, as because, by good fortune, he has time and again been exposed to mild subinfectious doses of the virus, and in neutralizing these has gained such immunity that later he is able to resist doses which would otherwise set up acute disease; and doing this that he raises not merely the specific but also the general resisting power of the organism.

If, therefore, we eradicate certain specific germs which to-day are widely spread, we are in danger of lowering the general resistance to disease; our bodies will not be so well educated to resist, and we shall be apt to succumb to microbes and diseases which in our present state are incapable of attacking us.

It follows that I imagine no Utopia from which infection will be banished; only a state of generally improved conditions of existence in which the exanthemas and the severer infections will be much reduced in their incidence, and the active curative work of the physician will be definitely reduced, the preventive work as definitely increased. Now, although the bacteriologist, detecting tubercle bacilli in the milk of a cow, by bringing about the compulsory slaughter of the beast prevents, it may be, a series of infants from succumbing to tabes mesenterica, that bacteriologist—virtuous as has been his action—cannot bill all the families of a particular milk-route for what he has saved them; cannot say to the parents, "The estimated value of your child's life to you and to the community has been officially estimated at so much, the chance that it would become infected from this particular cow was such and such, wherefore you owe me so much." The idea sounds absurd. But, as a matter of fact, the bacteriologist has accomplished all this, and if the individual cannot be asked to pay, it is for the community to show its appreciation. The more medicine becomes preventive, the more incumbent does it become on the community and the state, rather than on the individual, to subsidize the medical man.

I am no socialist, far from it. To me the doctrine that all men are born equal and are equal is as repugnant as it is manifestly false. How could we hope for progressive development, for the advance of our race, if all were at the same dead level; and if, notwithstanding the improvement in the individual, brought about by wise course of life in favorable surroundings, his offspring were after all only equal to that of the individual injured by unfavorable surroundings? The idea is unnatural, is contrary to the knowledge of evolution. It is on the face of it idiotic to maintain that the child born with the stigmata of congenital syphilis is equal to the child of sound parentage. That all be given, as far as possible, equal opportunities, that all be given a fair start, is quite another matter. If, therefore, I recognized a likelihood that the conversion of medicine into a public service would reduce all medical men to a common standard, no one would offer more active resistance. But I foresee that it means nothing of the kind. We are thus, I firmly believe, within measurable distance of the nationalization of the medical profession. I want you, gentlemen, to realize this, to face it clearly, and, what is more, to be prepared to help toward its accomplishment, living lives that will at once be a credit and a help to all our body. Such a momentous change should come from within the profession, not be forced on us from without.

I am not alone in this opinion; there are, I feel assured, others on this platform, members of your faculty, who are equally convinced that this has to come.

EUROPEAN PROGRESS IN PUBLIC HEALTH WORK

For what are the signs of the times? We on this continent call ourselves progressive, and we are progressive, but in this matter the Old World is leading the way. It is in no sense derogatory to us of the New World if, busied with the vast task of settling and establishing a continent, older countries across the ocean with greater leisure are far beyond us in certain directions. We here, for example, are still in a medieval condition as regards our Public Health Service. Individual cities, like your own, may be striving valiantly to place health matters on a proper footing; but take the country as a whole, and what do we find? Instead of securing those who have expert training as municipal health officers and paying them well, your ordinary municipalities elect either the youngest and rawest practitioner in the district or the man who has been a failure in private practice, to whom the shamefully inadequate stipend doled out by a grudging municipality is better than nothing. With such incapable minor officials, the state board of health, however capable its higher officials, is constantly impeded in its efforts. Here Germany and England are far ahead. Take the British conditions, which I know best. There every municipality must have its trained health officer, possessing a diploma of public health of an accredited university, and those posts are so well paid that I know from experience that universities have difficulty in procuring the best men to fill their professional chairs in hygiene, because the stipends afforded by the largest cities and more populous counties are so high that the attractions the universities can afford are insufficient. There is thus developed in Great Britain a definite career in preventive and public medicine, which to-day is attracting to it scores of the brightest of our men—a public service with definite grades and opportunities for promotion, with office dependent on capacity, independent of local and party politics, with permanency of tenure and popular respect. Bumbledom, it is true, does not love it, but Bumbledom is forced to submit under fear of such pains and penalties that perforce it cleans up its house and its back yard and reduces its infantile and other mortality.

This, however, as doubtless you all know, has been put into the shade by the further developments of the last few months, marshalled by Lloyd George. It is difficult to arrive at a sober, disinterested opinion regarding Lloyd George, so strong is the feeling he has aroused one way or the other. It seems impossible for any Englishman to appreciate his correct measure. If one can arrive at any judgment from the parliamentary proceedings, say by studying the *Times*, there can be no doubt that those proceedings and the tone of public life in Great Britain have painfully deteriorated since he and his friend Winston Churchill have come to the fore. Doubtless, were I in the old country, with certain innate conservative tendencies, I should cordially loathe him. Seen dispassionately from a distance, he appears to be that rarest of combinations, a ranting demagogue possessed of constructive powers. In establishing the eye and artisan insurance, he was, it is true, only following the lead of Germany, but his insurance against sickness has followed distinctly original lines. Briefly, he said that this payment on the part of or on behalf of the artisan and his family for insurance against sickness led to other obligations. If the government made itself responsible for payment for disability, it must provide the medical attendance, must see that the sick man or woman received due care according to a definite scale; and that this must be provided by the state. Thus to-day in Great Britain there is compulsory insurance against sickness and disability for all those whose earnings are below a certain amount, and in return the government provides medical attendance. The medical men in any district who accept the government terms become in this way servants of the state. The worker, male or female, is given the power of selecting his medical attendant from the panel, and having selected him he is paid by the government at the rate of something under two dollars per year per head. His interest, therefore, is to preserve the health of his clients—the less active sickness there is the better for him and for everybody. There are, I should add, special payments for drugs, maternity cases, tuberculosis, etc., which here I need not enter into.

So, after a sharp and very bitter campaign, medical conditions in Great Britain have been revolutionized. What must impress those who have followed the fight put up by the profession is that our brothers across the water were not opposed to the principle of Lloyd George's measure; on the contrary, they were ready to admit it. What aroused their fury was the way in which the bill was introduced; the way in which they, brought up to glory in their professional independence, were forced to convert themselves into public servants without so much as a polite "by your leave"; were told what should be the registration fee without consultation. To modify slightly an old saying, it was not what Lloyd George did, but the nasty way in which he did it. Wherefore, at first they refused to eat the Welshman's leek, but after it had been cut down somewhat and served in a more acceptable manner they eventually consumed it with fair grace. Now the measure has become law and matters are in process of adjustment. For example, the hospitals, both great and small, in Great Britain as here, have been established and are maintained by the voluntary contributions of the well-to-do. To-day, these supporters of the past are refusing further aid, on the ground that, as the rich are being heavily taxed by the government to meet the expenses of the new state of affairs, and as the government has made itself responsible for the sick poor, it and not they must bear the cost of medical charities, and must either make the hospitals complete state institutions as in Germany, or must afford so much per diem for each patient treated in the wards and in the outpatient clinics. It is doubtful if the government will consent to "taxation without representation"; whether they will pay for hospital maintenance without having a controlling influence on the hospital board. They must, it would seem, eventually obtain this control, and the nationalization of the hospitals must be a matter of the near future.

See what this signifies. The leaders of the profession are on the staffs of the hospitals. Men who have their paying patients among the well-to-do have refused thus far to accept the government contract and enter the public service. These leading physicians and surgeons will find themselves in the position of either resigning their hospital posts (which, when one considers what hospital opportunities and hospital positions signify, appears to me to be the unlikely course), or of continuing to serve, but now as government officials.

THE IDEAL OF SERVICE IN MEDICAL PRACTICE

Surely, therefore, and by no means slowly, Great Britain is embarked on a course that can lead only to medicine becoming a state service, just as are the army and the navy. From what we know of our brothers across the ocean, we may be sure that they will proceed by compromise; that they will be practical rather than logical in their advance. For long there will exist side by side the state practitioners, paid largely by stipend, and the private practitioners, consultants, surgeons, and specialists, paid by fee; but as the public medical service grows in extent it will grow in importance and desirability. There will be grades in the service, with possibility of promotion; valuable hospital and administrative posts to be filled. Inevitably the status of the members of the government service will come to be regarded as superior to that of the private practitioners. Once the world and his wife recognizes this, there will be no further difficulty: the whole profession will lapse into public service. It will, indeed, be exactly as with the army and navy. Your general or admiral, even your colonel or your commander, does not take his place in society and is not esteemed according to his wealth, but according to his position as a servant of the nation.

For this, gentlemen, we must realize: The race for wealth to-day is not a race for dollars; nor, after a certain point is reached, not difficult of attainment, is it a race for what dollars will buy. It is eventually a race for social status. If we can secure this status by other more honorable—or less vulgar—means, it is well for us. It is best for us to rejoice in our work for the work's sake and that alone; but if not all are able to attain unto this standard—and we must remember that ambition is healthy and laudable—then at least we do most good and least harm if, serving our fellows, we serve also the state, and develop a relative rank dependent on capacity and merit; comforted by the assurance that our work well done will bring us sufficient for our comfort, for the due education and maintenance of our family, and for our wife to meet the social enemy in the gate with due recognition. As medical men, what more ought we to need? There will be no socialistic dead level of sameness in such a future. Individual work and capacity will tell, though it will show itself mainly by position achieved and only secondarily by dollars.

This, it seems to me, is the future that lies open to us in this continent. It may be objected that here we have no Lloyd George and no workingman's insurance act to bring about the change. Quite so, but we have other influences. The development of an adequate and well-equipped public health service in every state of the Union is sure to come. And over a large part of the country, especially in the center and West, we have institutions whose influence undoubtedly is working toward the end I have indicated. I refer to the state universities and to the huge bonus which the states through these universities afford to the student who takes the six- or seven-year medical course. Even in institutions like your own, supported by private beneficence, I wonder if you realize that, while you pay what appear to be considerable fees, these fees represent only about half the cost of your education. The other half is a free gift to you from private individuals, and that not for your individual benefit but for the public good. This gift to the medical student, whether by the state or by the philanthropist, can mean only that the public recognizes that good medical attendance is a public need—aye, a public service. It is an indication that the community is prepared to go further—to call to itself an army whose function is to save life, not to destroy.

So, gentlemen, it comes to this, that, despite all the present-day temptations to which I have referred, to-day and in the future as even in the past care must be not for ourselves but for our fellows. If we desire not so much an upper seat in the synagogue as a serene mind and self-respect as the greatest of worldly possessions, let us not trouble ourselves about money-making. With your training, all that is necessary will come to you—you need have no fear.

I happened a few hours ago to come across once more a short address which Rudyard Kipling delivered to the students at McGill University six years ago. I do not think I can conclude better than by quoting some of his words:

> Money dominates everybody except the man who does not want money. You may meet that man in your farm, in your village, in your legislature. But be sure that, whenever and wherever you meet him, as soon as it comes to a direct issue between you, his little finger will be thicker than your loin. You will go in fear of him; he will not go in fear of you. You will do what he wants; he will not do what you want. You will find that you have no weapon in your armory with which you can attack him; no argument with which you can appeal to him. Whatever you gain, he will gain more. . . . If your wealth is necessary for you, for purposes not your own, use your left hand to acquire it, but keep your right hand for your proper work in life.

Gentlemen, may you fare well in your life work.

SURGICAL PATHOLOGY *

WILLIAM COGSWELL CLARKE, M.D.
NEW YORK

THE LACK OF AND THE NECESSITY FOR THE CORRELATION OF SUBJECTS IN MEDICAL EDUCATION

In the study of medicine each decade finds an increase of prescribed courses in the curriculums of the leading medical schools of the country. Not over thirty years ago instruction in pathology was given by the professors of medicine and surgery. The establishment of the chair of pathology was the first step from the custom of many years. Soon the chair of bacteriology was recognized as necessary, and a little later clinical pathology came into being. These topics came into prominence when an increase in knowledge made them too cumbersome for the professor of pathology and his staff to teach, burdened as they were with the constant increase in details in their own department. This increase in topics was not confined to offsprings of pathology alone, but was happening in all the major subjects. In surgery, there are found gynecology, genito-urinary, orthopedic, and oral surgery, all due to a widened scope and knowledge of the parent subject. These branches are well established in the minds of the practitioner and his patients, as shown by their recognition of the specialist, who is simply the ultrarefinement of the surgeon-barber of the sixteenth century. In his endeavor to be the possessor of the latest knowledge necessary for the best results in treatment, the embryo practitioner found that, on account of the unlimited mass of facts confronting him, he must choose one branch and confine himself to it. The medical schools, in the proper performance of their duty, provided instruction and suitable courses in these topics.

In the old days the professors of the various subjects, even of anatomy, were practitioners, each comprehending what every other professor in his medical school was teaching the students. Thus unity of purpose existed, a distinct advantage, in that the medical student from day to day understood without effort the semiclinical lectures and the relations of one subject to another. It must be conceded that the simplicity of subjects at the time also led to the same end.

Dating from the Renaissance in the study of anatomy and medicine, laboratories devoted to anatomy first appeared. At that period medical schools existed as establishments in relation to the laboratories of anatomy. As each subject in medical education was born, laboratories for each scientific branch were provided, since there were always scientists, especially in medicine, who desired to investigate things for themselves, as well as those desirous of augmenting knowledge by research. Moreover, in addition to the old-fashioned semiclinical lectures, to afford instruction by personal observations in the rapidly developing topics of medicine, laboratories and their adjunct demonstration rooms, were necessary. With the appearance of laboratories and laboratory workers, akin to pure scientists, on the teaching staffs of the various departments, and because the practitioner-instructors properly continued to deal with clinical subjects, two teaching groups were, unfortunately, formed in each medical school.

Because of this tendency of the scientists, wrapped up in the mysteries of the pathologic laboratory, to slip further and further away from the point of view of the clinician, the medical student is apt to be the sufferer. Many pathologists seem to forget that the majority of students who come before them intend to practice after they graduate. The fact that the individual elects to settle down in the enclosed life of the laboratory, deal in pathology, and teach a more or less abstract science indicates his mental attitude. There are many exceptions to this rule and there have been many in the past; however, it is fair to state that the interests of the pure pathologists are not those of the clinician.

On the other hand, with few exceptions, the clinical professors are out of touch with the laboratory. The countless clinical teachers on the staffs of the many medical schools of the country are not aware of what the pathologists of their individual schools know and teach on a given point. Because of this, the student fails, often until it is too late, to realize that he is studying pathology in order that he may have a better understanding of surgical and medical conditions and processes. The pathology that the student absorbs he is apt to carry in a separate niche of his brain, and his surgery and medicine in others, thus not having the study of pathology to assist him to the best advantage in his study of surgery and medicine.

From the point of view of medicine, the instructor in pathology may be presenting to the students gross specimens, among which may be a lung covered by fibrinous exudate. Should the instructor state, "The physical signs the patient has recently shown are as follows . . . and here before you is this beautiful demonstration of their cause," think of the mental picture the student by necessity conjures up when the gross pathologic specimens seem again to be alive before him, as in an actual clinical case. When this point is brought to the attention of the teacher in pathology, he is apt to reply, "That is

---

* From the Department of Surgery, College of Physicians and Surgeons, Columbia University.

the duty of the professor of medicine; I am expected to teach the abstract science of pathology." At the same time this teacher of pathology will feel that his domain is somewhat encroached on if the professor of medicine attempts the presentation of specimens to exemplify physical signs. If this deficiency in the teaching of pathology is brought to their attention many instructors of pathology reply, "These are but students; after they become practitioners they will obtain these associations of ideas in physical signs and pathologic conditions." If this be true, does not such an explanation intimate that correlation of ideas is always the best aid in learning? The same clinicians and pathologists will state that this or that prominent man was eminent as a clinician because in his younger days he had unusual facilities for doing necropsies, especially on the patients whose physical signs he had known from personal observation. Others may contend that these men possessed superior mental talents. Possibly so; but they directed their talents so that the point in hand was attacked from every possible side.

From the point of view of surgery, a clinical instructor in the routine of surgical teaching may present to the students a suppurative arthritis. At a remote period the pathologic staff of the school discourses in a purely abstract manner on the changes following the repair of abscess cavities, and possibly may mention that abscesses occur in joints. To return to the clinical aspect, the surgeon expounds on the necessity for drainage of the joint to limit as far as possible the toxemia; he may state that the usefulness of the joint will probably be more or less impaired, even speaking of adhesions and the separation of the cartilages. The average student cannot bridge the gap and visualize the actual pathologic changes, logically thinking over the abstract teachings gleaned in the department of pathology. The pathologist, with the almost countless themes that must be covered in the allotted time, cannot pause to mention physical signs, clinical course, and the treatment necessary for each pathologic condition and process that is touched on.

The surgeon, on the other hand, with his mind riveted day after day on the purely clinical side, his time taken up with clinical duties, cannot be expected to give in detail and discuss at length all the vagaries of the gross and microscopic changes occurring and likely to occur from the day of the infection of the joint until healing is complete and the process has reached a quiescent stage. How may such a lack of correlation in teaching be compensated for?

THE RÔLE OF SURGICAL PATHOLOGY

So far as surgery is concerned, the subject, surgical pathology, should be the connecting link in the student mind between surgery and pathology, in order that the student may readily correlate each point as it is presented. Surgical pathology is really a study of the clinical aspect of the pathologic conditions and processes coming directly under the notice of the surgeon, and not matter abstracted from the domain either of pathology or surgery. Surgical pathology, for example, should show the student how a given physical sign in a clinical process may be explained if the pathologic condition is understood.

The importance of this correlation of ideas for the medical student is not universally realized, nor is there any general comprehension of the rôle that surgical pathology should fill in medical education.

THE PERIODS FOR SURGICAL PATHOLOGY IN THE STUDY OF MEDICINE

Surgical pathology should commence as an introduction to surgery and its special branches, at the period when the student is well advanced in his study of introductory subjects, such as gross and microscopic anatomy, physiology, and physiologic chemistry, and at the time when he commences bacteriology and pathology, in order that these given subjects shall be studied side by side. This period is usually reached some time during the second year at the medical school. To round out his surgical course to the best advantage, moreover, surgical pathology should be reviewed in the last year. In the student's introduction to surgery, the subject, at best, is a new field in his education, but after he has had a period of time to correlate whatever he remembers, after he has seen considerable clinical material, attended many operations and followed their subsequent clinical progress, and heard lectures on surgery, he will grasp the subject from a much broader point of view.

TIME TO BE DEVOTED TO THE SUBJECT

To make a lasting impression on the student mind, the introductory course must extend over a considerable period. At least three hours a week throughout the year are necessary, of which two one-hour sessions may be devoted to discussion in the class-room, and one hour to laboratory work or clinical observations.

In the second period, two two-hour sessions of laboratory work for a quarter of the year are sufficient. This time may be evenly divided between the laboratory of the university hospital to facilitate instruction in human tissues, and the college laboratories of surgical pathology.

COURSE IN SURGICAL PATHOLOGY; TOPICS FOR STUDY

The student, during his first period, should read the given lessons in a text-book on surgery and study the pathologic processes in a text-book on pathology; this should be followed by conferences with the instructor, combined with laboratory work and the observation of clinical material.

The course should commence with one of the simplest possible processes and conditions that are departures from the normal, such as a simple injury; for example, an incised wound. The study of this will lead the way to all the interesting phases of repair, bringing in the more and more complicated forms of injury involving the various tissues of the body—skin, connective tissues, mucous membrane, muscle, bones, nerves, vessels, and the parenchyma of the various organs. The student has an opportunity to learn just what the injury does to the living tissues and to observe the pathologic processes and conditions that supervene. The discussion in the class-room must of necessity cover a wide range—gaping of the wound, hemorrhage, exudate (coagulated or fluid), proliferation of tissues, clinical terms, regeneration and repair, ideal, delayed and abolished healing, inflammation, infection, scar tissue, and the interference with function.[1] In other words, much more than the actual study of the repair of an incised wound must be touched on by the students.

Attention is here called to the fact that inflammation as a topic has not been mentioned. It seems to make more impression on the students and to be better understood if the process is treated merely as an incident in all injuries, varying simply in degree. Confusion is thus avoided to a certain extent in the student mind between what the clinician understands by inflammation and what the pathologist teaches.

Under supervision, in the laboratory, a student may make a small incised wound in an anesthetized animal. The entire student section may see the wound gape, and the clinical changes presenting various physical signs may be followed to the termination of the process in repair. Microscopic sections, taken at the various stages of repair following the injury or operative wound, from both animal and human tissues, will serve to illustrate and furnish a basis for discussion of the physical signs and actual pathologic processes present. The physical signs must be considered with special reference to the pathologic conditions that produce each sign. The clinical course observed from day to day affords an opportunity to discuss the consequent change in the pathologic conditions. Coincidental variations in the physical signs must be dealt with at length.

To emphasize the rôle that infection plays, a hypothetic injury should be discussed from which all outside irritants may be excluded. In this way the cellular changes pure and simple, due to the injury alone, may be learned. The introduction of a hypothetic "non-irritating foreign body" into the tissues may be studied. The cellular reactions in such an experiment may be contrasted with those that occur in the presence of an "irritating foreign body" or one that carries various chemical elements into the tissues. This paves the way in the student mind for an understanding of the complicated and varied reactions of the living animal tissues in which infections are present, especially surgical infections. Comparisons may be constantly drawn between the hypothetic simple wound, a wound containing a "non-irritating foreign body," and, finally, an infected wound.

All the possible terminal phases of the surgical-pathologic process should be pointed out in detail, since these suggest what various forms of treatment might avail. It is not the idea that the treatment, as such, is to be taught, though to lose sight of treatment is a bad beginning for the medical student. His great rôle in afterlife, aside from attempting to prevent pathologic processes, is to treat them, and that he cannot treat intelligently unless he understands as much as possible, should be instilled into his mind. This attention to treatment, by necessity not touched on by the instructor in pathology, is one of the many little things that tend logically to connect, in the student's mind, pathologic matters with the clinical features of medicine and surgery.

In addition to the study of injuries and the repair of the various tissues compromised by the so-called surgical infections, a consideration of the special infections, such as the surgical aspects of tuberculosis, syphilis, anthrax, glanders, tetanus and hydrophobia, should also be included, and the surgical terms, cellulitis, abscess, furuncle, carbuncle, toxemia, septicemia, erysipelas, aneurysm, ulcer and gangrene, should be defined and explained. The study of diseases and injuries of anatomic structures, such as vessels, bones and joints, including synovial membranes of tendon sheaths and bursae, and the clinical-pathologic aspect of tumors, must also be covered at length.

Some time must be spent in discussing a normal as contrasted with a pathologic individual who has been subjected to an injury. The rôle that vascular changes and disturbances of metabolism play in the formation of ulcers and in gangrene must be emphasized. The bearing that the common constitutional diseases have on infections and the repair of operative wounds, is also important. For the sake of discussion, [illegible] ation [illegible] election on a simple hernia, restrained [illegible], in [illegible] person under 40 may be chosen. The q[illegible] hei[illegible] or not such an operation shall be done on a person who has chronic nephritis, a heart lesion, diabetes or pulmonary tuberculosis accompanied by cough. Next may be considered an operation on a patient with the same conditions, for a simple inguinal hernia too large to be restrained by a truss; to make the problem complete, a strangulated inguinal hernia, an operation of necessity, should be mentioned. The advisability of operations on pathologic persons should be discussed, regarding not alone the repair of the wound, but also the effect of the anesthetic on organs of absorption and of elimination, the shock of the operation, and the elimination of tissue toxins.

In the second period, when the students meet the instructor in surgical pathology, best in the students' fourth year, very general topics should be taken up. Pathologic material from patients whom the students have seen both clinically and at operation serves well as a basis for discussion. For example, observation of coagulated exudate on the peritoneal coat of an acutely inflamed appendix will lead into the general topic of adhesions, peritonitis, the significance of coagulated and fluid exudates found at the time of operation and their relation to the prognosis. Microscopic sections may also be shown of the same appendix covered with exudate. At the time, sections of adhesions from other conditions indicating different characteristics may be on exhibition.

If there is in the given medical school a course in surgical technic, in which animals are used as subjects, the possibilities in teaching surgical pathology become almost limitless. It is of great advantage for the students to see for themselves the repair of tissue in common abdominal operations, in which healing has been almost ideal. Necropsies in operative abdominal conditions in man are always made under circumstances of peritonitis or some other unfortunate pathologic process. On very rare occasions, the surgeon, because of the necessity for a subsequent laparotomy, chances to see the result of his primary operation. Every surgeon realizes how infrequently these opportunities occur. By necropsy of animals that are making a good recovery as early as thirty hours, and at later intervals, after operation, the students may be shown the suture line of an intestinal anastomosis. Attention may be called to the integrity of the abdominal wall, and practical demonstration may be made of the stress the healing wound will withstand. Pointing out the errors in technic, such as resulting hemorrhage, intestinal leakage with the subsequent peritonitis, and excessive narrowing of intestinal lumen owing to too great invagination of intestinal wall at the time of suture, impresses the students with the importance of guarding against these dangers. This affords the students actual demonstration of the ideal and pathologic conditions that will obtain in similar circumstances in human abdominal cases shortly to be cared for by them as hospital interns.

METHODS OF INSTRUCTION

In teaching surgical pathology, the instructor must decide whether he shall be dogmatic or shall constantly indicate that there are but very few facts and that much is theory or hypothesis. Certain instructors believe that they undermine the confidence of the students both in their teacher and in medicine if they continually point [illegible] that there [illegible] many differences of opinion. Others [illegible] that stu[illegible] [illegible] not capable of judging or deciding [illegible] emselve[illegible] [illegible] ven several hypotheses attempting to [illegible] a clin[illegible] [illegible] non.

These two points of view are obviously short-sighted. As to the first, there is always repetition in teaching, and since several instructors may present to the students their opinions, failing to state them to be but their opinions, the students, when they confer together, as they are bound to do, find that the several statements are at variance. Naturally there is confusion, and their confidence in their several instructors is certainly undermined—just the thing each teacher sought to avoid by being dogmatic.

The second point of view, that the student cannot discriminate, is certainly vicious in itself. In the classroom the student may be blamed for not being able to think; and often as not (as an expedient) he is not allowed to; but, in the first clinical case that the student deals with, the instructor expects him to think and reason both in diagnosis and in treatment. Certainly the embryo physician must often use his wits, and the earlier he commences the better.

A medical student is a postgraduate student, and it is the duty of the instructor to state frankly what is fact and what is theory in discussing any phenomenon. If the instructor so elects, he may state his personal opinion of which is the best theory, assuring himself that the student understands it to be merely an opinion. The discussion of the instructor's opinion tends to widen the student's horizon, to fix the subject in his mind, and to encourage him to think. Many instructors will be disturbed by the free expression of a student's ideas, but it must be realized that in a class of seventy or eighty men many types are present. Their manner in meeting the instructor varies widely, depending on their early environment and education. All these differences must be allowed for by the instructor.

The main thing is that the instructor must realize that he cannot teach unless the student is willing to learn, and the more the instructor leads the student to reason, however skeptical he may be of the student's ability, the better teacher he is.

It must be realized by the instructor in surgical pathology that his subject is far from being a mathematically exact entity. There is but little that the student may learn by rote. And in the student's entire education, even though he be a college man, there are but few subjects that touch on a wider range of sciences than surgical pathology. Because of this, one of the simplest rules of teaching must constantly be borne in mind; that is, to be always informed of the student's conception of each subject from day to day. Simple questioning of the student, the ordinary method of instruction, is not sufficient. Leading the student into discussions and into asking questions concerning the physical signs and pathologic conditions instantly informs the instructor of the progress the individual student is making. Any one may make a seemingly clever answer, but it takes a well-oriented student to ask a sensible question.

Frequently by the very token, as stated, that surgical pathology, its teachings and the fundamental principles dealt with, are far from mathematical entities, it is difficult for the students to realize the wide variations in the physical signs, clinical course, symptoms and pathologic processes and conditions of even type diseases. They may read a given text description of a disease, pneumonia for example, and possess a fair working idea of the morbid process, be able to answer questions with reasonable intelligience, and fail miserably in diagnosis. The given clinical case did not happen to fit the typical text-book description which the students had read. On the other hand, the students do not fall into this pit of a case if presented to them by the clinician. The students realize that this given patient chances to present this or that peculiarity. They also realize that the next case of the same disease may present other peculiarities. When teaching was almost entirely clinical, as in the past, this very fact made the study of type diseases somewhat simpler, although they were less understood. The students read up the theory of the disease subsequent to each clinic and appreciated the similarity of points found in the text and those shown in the clinic. If these clinics are not given in the course of surgical pathology, each student of the class will have a different mental picture of such a condition as an infected wound, for example. The composite of the entire class would likely possess a very good concept of infected wounds, though the ideas on the subject of any one student would not be at all satisfactory.

This may be tested out in a simple manner for the purpose of informing the instructor and for a demonstration to the students to show the students not so much what they do not know as the pitfalls in their path and how they may be avoided. The written descriptions of an infected wound obtained from each student may be compared before the class. The instructor may describe to the students any infected wound that occurs to him and ask them what he has been talking about. An infected wound may be presented in the clinic and the instructor may ask each student in turn, "What is the pathologic condition?" He will be amazed and pained at the dissimilarity of the written descriptions, surprised to learn that but one or two recognized the condition he has described and be shocked to hear but two or three mention the correct pathologic condition. An instructor's first impulse is to complain of the ignorance of the students and to exclaim that they will never learn anything. He must, however, realize the root of the trouble and demonstrate the matter to the students, letting them see for themselves that they must appreciate the wide range of possibilities for injuries and disease and must also bear this in mind when reading from text-books. The students must be brought to see that if an infinite number of pathologic processes and conditions could be observed, every possible variation would be exemplified. For convenience in classification and for description, mile-posts along the clinical and pathologic road have been selected as types and have been given the various familiar clinical and pathologic names. By necessity there are pathologic conditions and processes not occurring at a mile-post, but nearer one than another; from such a mile-post will the process or condition receive its name.

Certain students readily grasp these facts and easily outstrip their companions in the study of surgery; while others, possibly those who have excelled at college in the classics, fall behind and never even reach the plane of apparently much poorer men. This often tends to discourage many who before have had no trouble as students, but cannot properly correlate the knowledge necessary to thoroughly understand the complex biologic facts that exist in living tissues from the time of the incident of an incised wound until its healing is complete.

CONCLUSION

Since surgical pathology shall bridge for the students the wide gap between pathology and surgery, the instructor should be trained as a clinician, and, in addition to being a person with interest in clinical matters, he must at the same time spend many hours in the laboratory, studying both the gross and microscopic aspect of specimens from surgical conditions. Regarding these specimens, strict attention must be paid to the clinical course, the physical signs presented, and the outcome following operations or other treatment. Constant experimentation, involving the fundamental principles of surgery, should also be conducted, in order that, so far as possible, the instructor's knowledge of his subject shall be from his personal observations.

The surgical pathologist is to directly connect the thoughts of the student with the pathologic aspect of surgical conditions; he can therefore best serve his purpose in such a rôle by being an integral part of the department of surgery, making his associations more intimate with the teaching staff of surgery. Thus the surgical pathologist has more direct access to clinical material, and with the laboratories now supported by the department of surgery in many medical schools, facilities to study pathologic material are available. The association of the surgical pathologist with the clinical staff of the department of surgery is also by this means made more intimate; the laboratories of surgery become a clearing-house, as it were, of the clinician for his surgical material. Because of this, the clinical aspect of any concrete clinical condition, by discussions with clinicians, is kept fresh in the mind of the surgical pathologist, and he is not led away by the more or less philosophic and abstract point of view of the pure pathologist.

The field of the surgical pathologist is an exceedingly interesting one because of its concentration, enlivened by the clinical aspect, enriched by facts gleaned from microscopic examination of clinical material obtained at operation and constantly reviewed in the subsequent clinical course. Surgical pathology should introduce to the students fundamental surgical principles and prevent any separation of ideas and concepts of both normal and pathologic processes and conditions as taught in the departments of anatomy, pathology, bacteriology, physiology, physiologic chemistry and of surgery in medical education.

437 West Fifty-Ninth Street.

TEACHING OF OTOLARYNGOLOGY

REPORT OF COMMITTEE APPOINTED TO CONSIDER THE BEST METHODS TO BE FOLLOWED IN THE TEACHING OF OTOLARYNGOLOGY IN UNDERGRADUATE AND POSTGRADUATE SCHOOLS

J. STITT WISHART, M.D.
TORONTO
CHARLES W. RICHARDSON, M.D.
WASHINGTON, D. C.
S. MACCUEN SMITH, M.D.
PHILADELPHIA
Committee of the Laryngological, Rhinological and Otological Society

The subject assigned to us for our deliberation naturally divides itself into two distinct parts, and yet, in the final analysis, the postgraduate teaching is closely dependent on the thoroughness of the undergraduate work.

TEACHING OF OTOLARYNGOLOGY TO UNDERGRADUATES

In order to ascertain what methods are followed and what views are held in the various leading universities of this continent on this question, your committee submitted a series of questions to the professors of otolaryngology in forty of the leading institutions, the list of these being compiled from the Carnegie Foundation Bulletin 4, entitled "Medical Education in the United States and Canada."

The questions were as follows:

1. Should the "course of instruction" be extended over one or two years?
2. How many hours should be devoted to this "course of instruction?"
3. What proportion should be clinical and what didactic?
4. In what order should these be given?
5. What should be the limits of such a "course of instruction" having in view the necessities of the general practitioner, and the proper balance of the subjects of a medical curriculum?
6. Should "operations" form part of such a "course of instruction?"
7. Should a separate examination in Otolaryngology form an integral part of the final examination?

N. B.—In answering the above questions, which are intended to ascertain the personal views of those responsible for otolaryngology in the leading medical colleges of the United States and Canada, it is desirable to indicate briefly also to what extent these personal views are carried out in the institutions with which the writer is connected.

Replies were obtained from some thirty-one institutions, including over twenty states and provinces so that the opinion elicited may be considered fairly representative. In perusing these reports, your committee was agreeably surprised to find so little divergence in either practice or opinion as the replies revealed, and have therefore the greater confidence in submitting the resolutions which form its conclusions.

We regret that we are unable to elicit satisfactory information as to the amount of "individual instruction" given to each student. Where the number in the classes are considerable (and if possible that number should never exceed six students), as Mygind[1] points out, "the student is apt to acquire superficiality in the examination of the patient. This fault is undoubtedly in many cases due to the teacher not having sufficient time to take each pupil individually and teach him all the details he should observe."

We note also that the idea still lingers in the minds of some of our leading instructors that didactic lectures form an adequate means of instruction. About one-fourth of those reporting asked for equality between didactic and clinical instruction. Surely this cannot be right. The regions involved in otolaryngology are such as lend themselves least readily to demonstration by lectures, or even by lecture-clinics. It is only in so far as the student receives "individual instruction" on the living subject, that he can acquire an adequate knowledge of his subject in the limited time which can be spared in the overcrowded medical curriculum.

This "individual instruction" requires time, patience and competent assistants, but these are well worth the expense involved, as by properly instructing the student of medicine in otolaryngology we will do much to avoid the conditions which now lead to the foisting of vast numbers of what we may style pseudo specialists on the public.

Another point which your committee deems worthy of criticism in dealing with these reports is the scope of the instruction with regard to text-books. Such a course should get as far away from the text-book as possible. We cannot in the least agree with the gentleman who reported, in answer to Question 5, "that the contents of the required text-book on these subjects should be covered *chiefly by recitations.*"

Every student of medicine has a right to be graduated primarily as a general practitioner. The first task of every general practitioner is diagnosis. No amount of text-book recitation will develop the ability to diagnose correctly in otolaryngology, unless there go beforehand the visual knowledge of the normal as contrasted with the abnormal, the education of the eyes, ears and fingers. This education means actual work on the patient and the "course of instruction" should therefore be almost wholly clinical.

---

[1] Mygind: Brit. Med. Jour., Aug. 24, 1912.

By Question 5 we hoped to elicit a sufficient answer to a difficult problem. With the daily advance of medical science, new subjects are demanding, with loud voices, admission to an already overburdened course, and even in those universities in which the course is one of five years, it is being found needful to relegate some of the science subjects to the preparatory course, so as to give the student time to digest what he sees daily in the wards. The best of judgment is therefore called for in determining what shall form a part of the minimum curriculum in medicine.

On the other hand, as Gradenigo[2] has pointed out, "what doctors need in their daily practice should be made compulsory, without expecting them to be familiar with complicated examinations and operations." This states in a nutshell what should be included in the "course of instruction" in otolaryngology. The student, therefore, should be made thoroughly familiar with the anatomy, should be taught the use of the instruments of examination, should be able to recognize the normal parts, should be familiar with their appearance in the acute inflammation and in the commoner chronic affections, and finally should be able to recognize and understand the principles of treatment of the acute affections.

With this information in his possession he will have a solid foundation on which to build his superstructure, will be able to read his text-book in connection with a given case intelligently, obtain a comprehensive knowledge of the condition of the various organs of his patient, and, finally, be in a position to secure early and useful assistance from the specialist. Inability to examine a larynx has often led to a failure to recognize malignant disease in its incipient stages, and many examples will occur to all of us in which the lack of training of the student has been to the great suffering of his patient and the disgrace of the practitioner. Such a course will not be complete, however, without instruction from his professor as to what symptoms demand the skill of the specialist, and the unwisdom and criminality of failure to refer the case for examination by the thoroughly trained specialist, when such symptoms arise.

The last question elicited practically unanimous replies that a separate examination conducted by the professor of otolaryngology should form an integral part of the final examination. The association of a question or two on the ear, or throat, on the paper in surgery must be relegated to the past.

Your committee therefore begs to recommend for your adoption the following as the minimum requirements of the undergraduate course in otolaryngology:

RECOMMENDATIONS FOR MINIMUM REQUIREMENTS IN UNDERGRADUATE OTOLARYNGOLOGY

1. Each student of medicine is entitled to receive sufficient instruction in otolaryngology to enable him to deal with the parts concerned as intelligently as with the rest of the human body.

2. For this purpose he should be familiar with the anatomy of the parts, possess a practical working knowledge of the simpler instruments of examination, be able to recognize familiarly the normal appearance of the structures, be practically acquainted with the pictures presented by the acute inflammations, and the commoner diseases of the organs involved, and how to treat the same. He should, further, be instructed to recognize the symptoms of serious complications, the wisdom of early associating the greater knowledge of the specialist in the care of his patient, and the dangers associated with all operations on the parts involved, except in the hands of the competently trained specialist.

3. For this "course of instruction" a share of each of the two final years of the medical curriculum is essential.

4. The said "course of instruction" should embrace both clinical and didactic teaching, preferably intermingled, the clinical to be greatly in excess of the didactic—at least in the proportion of three to one.

5. Clinical instruction should be given to small groups of students, preferably in classes of six, each receiving individual instruction, and this together with the didactic work should extend over a period of at least forty hours in the time of each student in each of the two years.

6. Operations should not form any part of the preceding course, except that in so far as may be possible, each student should be permitted to assist at the performance of the simpler varieties, that he may become practically acquainted with the methods of procedure and the objects sought.

7. A special separate examination in otolaryngology, preferably clinical, conducted by the professor of otolaryngology, should form part of the final examination in medicine of every university, and every licensing body.

8. A copy of these resolutions should be forwarded to the medical faculty of every university and college of medicine, as well as to every state or provincial examining board, in the United States and Canada.

II. TEACHING OF OTOLARYNGOLOGY TO POSTGRADUATES

The second part of this report concerns postgraduate instruction in otolaryngology, and while the former was aimed at the production of the well-rounded general practitioner, this must endeavor to achieve the evolution of the scientific specialist.

The subject is much to the fore on this continent and elsewhere. Last year the *Journal of Laryngology, Rhinology and Otology* published a series of able articles on the education of the specialist in throat, nose and ear disease, in Denmark, Germany, Italy, Austria-Hungary and France. In Great Britain it formed a topic of general discussion at the Liverpool meeting of the British Medical Association. On this continent, it has led to the publication of recent papers by Shambaugh,[3] Ellett,[4] Cragin[5] and others, and formed the basis of an interesting discussion before this society two years ago, a discussion which led to the formation of the committee now reporting. A pronouncement by this important organization will therefore be quite apropos at this serious juncture, for we must not forget that with privilege comes responsibility, and this society, whose membership is so extensive and whose influence is so wide-spread, should—*noblesse oblige*—lead, not follow, in the making of an intelligent public opinion.

According to Mygind[1] the postgraduate education of the specialist on the continent may be divided into three stages: (1) a compulsory preliminary training at the university for a period of one term; (2) a postgraduate course at a university or hospital; (3) a service as assistant at a special public clinic.

We all know the facts, and we deplore them: now what can be done to face and overcome the difficulties of the situation? We must first decide what constitutes the standard of proper training, then provide for its acquirement, and finally bring such influence to bear on state legislatures as to secure the legal enactment that only specialists provided with this training may practice as such.

Those who have written on this subject are agreed that not less than two years should be devoted to preparation for practice as a specialist. This should be preceded, however, by one or more years spent in general practice, or better as house-man in the medical and surgical services of a good hospital, at least half the time being devoted to surgery. The specialist course itself must embrace highly specialized studies in the anatomy, physiology, embrylogy, pathology, physics and therapeutics which bear on the subject, operations on the cadaver, etc.

[4] Ellett: South. Med. Jour., January, 1911.

[5] Med. Rec. New York, lxxx,

The time required for this course will occupy at least six months. In addition the candidate must subsequently serve as a resident assistant in a special hospital or in a similar position in the special service of a large general hospital, for a period of not less than eighteen months, and to provide sufficiency of experience, the special clinic should work daily, and should have at least fifteen beds assigned to its use. In this connection it is well to insist that during the last six months of his service, the candidate shall act as a senior assistant in the major operations, and personally perform those less important.

Where shall such training be provided? Without doubt the scientific part must be placed solely under the control of the universities, for these are the proper bodies to provide postgraduate instruction.

To add a fitting coping-stone to the structure whose erection we are considering, the candidate should finally be compelled to present himself to one of the universities, supplying the postgraduate instruction indicated above, for examination on the work embraced in the entire course, and the successful candidate should be given a degree; that of Ph D., (Oto-Laryngology) has been suggested in various quarters.

The final step, that of securing legislative measures, would of necessity be difficult to attain, but public opinion will ere long demand that we be protected from the incompetent specialist, as we are now from the ill-trained dentist.

With regard to postgraduate teaching in otolaryngology your committee begs to recommend:

1. That the time has arrived to standardize the degree of scientific attainment, and of clinical training, which shall qualify those who wish to begin the practice of otolaryngology as a specialty.

2. That the report of this committee now submitted forms a suitable basis for such a standardization.

3. That a committee representing this society be appointed to work out the details.

4. That the other important associations of otolaryngologists on this continent, namely, American Laryngological Society, the American Otological Society, the American Medical Association, the Academy of Ophthalmology and Otolaryngology, be and are hereby invited to appoint representatives to act with the above committee from this society, so that the action finally taken shall represent to the fullest extent the consensus of opinion of American and Canadian otolaryngology.

CARE OF THE UMBILICAL STUMP

A BACTERIOLOGIC STUDY [*]

FRED L. ADAIR, M.D.
Assistant Professor of Obstetrics, University of Minnesota
MINNEAPOLIS

It is not my intention to consider the clinical aspects of infections which affect the new-born infant through the umbilicus. The seriousness of such infections is well recognized. The more severe and fatal forms present clinical and post-mortem evidence which forces itself on the observer. The proof that milder types of infection originating in the umbilicus cause fever, jaundice, loss of weight and gastro-intestinal disturbances in the new-born infant is difficult to bring forward. It has been demonstrated that serious and fatal umbilical infections can exist and give no local antemortem evidence of their presence. It would not be unfair to conclude that milder forms could exist and the infant recover without local manifestations of umbilical disease. Such infections occur in isolated cases and in epidemic form in institutions. There may be the moist gangrene with the foul-smelling, putrefying cord, a simple omphalitis with a discharge of varying character, an ulcer lying between the folds of the skin at the navel, a more or less diffuse cellulitis, possibly with abscess formation. The arteries and veins may be involved with little or no local evidence of this condition. Infection of the arteries is more frequent and less serious than that of the vein which is almost invariably fatal. The septic form of umbilical hemorrhage may result from infection entering through this wound. Some of the more specific infections, such as diphtheria, tetanus and erysipelas may originate at this point. The much dreaded sepsis may enter and destroy the new-born babe and leave very little evidence of its entrance at this point.

In children born spontaneously, the cutting of the cord makes the only wound on its body, and this should be considered as important a wound as one which enters the peritoneal cavity. Other sources of infection must be admitted, but many of them are in no way under our control.

The care of the umbilical stump is something for which obstetricians and nurses are directly responsible. Are they fully aware of their responsibility? Certainly many of us would not care to have our peritoneal cavities opened under the same precautions which we take in severing and caring for the umbilical cord. This is especially true when we consider the great susceptibility of the new-born child to infection. Anatomically, the cord leads almost directly into the peritoneal cavity. The arteries are almost intraperitoneal and the postnatal thrombus forms an ideal place for the development of organisms. The vein, in addition to being closely associated with the peritoneum, leads directly to the liver and communicates with the large venous circulation. The lymphatics are in almost direct communication with the peritoneum. Wharton's jelly becomes virtually subserous by its extension within the abdominal wall.

The absorptive powers are great, as has been demonstrated by Epstein[1]—who used different chemicals on the cord and was able to demonstrate them in the urine within a very short time.

Clinically, there is abundant proof that fatal infections may enter through the umbilicus and rapidly overwhelm the new-born babe. Eröss[2] reported 1,000 cases, with fever in 43 per cent. and evidence of navel infection in 23 per cent. Roesing[3] in 100 cases found fever in 21 per cent. and umbilical infection in 9 per cent. Götzl in 130 cases found trouble with the navel in 13 per cent. Berend and Racz.[4] in 1,000 babies who were tubbed, found infection in 19.7 per cent., in 1,000 not bathed in only 9.3 per cent. Doctor[5] investigated a series of cases in which 420 infants were bathed, 33.15 per cent. of these had a febrile reaction and 16 per cent. showed infection of the navel. Of 462 babies with a long stump of cord, which were not bathed, there was fever in 25.83 per cent. and umbilical infection in 10.12 per cent. There was fever in 11.88 per cent. and navel infection in 3.46 per cent. of 230 infants with a short stump which were not bathed.

In 1896, Lambert[6] reported a series of 147 cases in which there were five deaths from infections originating at the umbilicus. This is a mortality of about 3.4 per cent. He was pleading for a better treatment of the umbilical cord. We all see such cases not very infrequently.

Dickinson,[7] in a most excellent and thorough consideration of this subject, collected from the literature more or less complete observations of over 10,000 new-born children. He says: "Fever due to navel infection, from 3.5 to 22 per cent., studied on 2,755 babies (the higher percentages in summer); well-defined general sepsis, 5.25 per cent., the review embracing 1,329 babies; deaths from sepsis, a full 1 per cent., the material being 6,011 new-born children. The ratio of septic deaths to early deaths from all causes varies between 15 and 40 per cent."

More recently, 795 cases treated in the Virchow-Krankenhaus by ligation and a sterile dressing smeared with oil showed inflammatory disease of the navel in 15, or 1.7 per cent.

In an endeavor to find some means of preventing these infections, I have been led to make some investigations which it is my intention to present at this time.

The first step has been to find out whether or not organisms are present on the cord and surrounding skin immediately after birth. It would be only natural to find them present.

Cholmogoroff[8] removed, with sterile scissors, pieces of the umbilical cord immediately after birth in five cases. Cultures made from these were all negative. He also investigated cases which were treated by different methods and found various staphylococci, once the streptococcus and various non-pathogenic organisms. He concluded that the cord was sterile at birth and that the germs were introduced from without.

It would be very easy for the surface of the umbilical cord and of the child's abdomen to be contaminated with any organisms present in the mother's vaginal tract or on the external genitalia. If they were on the surface, it would be very easy for them to grow and invade the tissues.

In order to prove the presence or absence of organisms on and around the cord immediately after birth, the following procedure was employed:

A platinum loop was used to scrape the cord and surrounding skin immediately after birth and before the cord was handled or manipulated in any way. Agar plate cultures were made from the material caught on the platinum loop. All these cultures were made under as nearly the same conditions as possible in the Elliot Memorial Hospital at the University of Minnesota. No attempt was made to isolate the anerobic organisms.

There were sixty-five cases examined in all. In seventeen of these there was no growth. Non-pathogenic organisms were found independently of any pathogens in thirty-three cases, or over 50 per cent. of those examined. Pathogenic organisms were found alone or associated with non-pathogens in twelve, or 19.46 per cent. Some variety of staphylococcus was found in eight instances and some form of the *B. coli* group in four cases.

The significance of this is evident. The cord and its surroundings show the presence of pathogenic organisms in nearly one-fifth of the cases immediately after birth. This is true where the cases are conducted amid the aseptic surroundings of a delivery room. The percentages might easily be much higher where less rigorous asepsis is carried out. This, of course, is no argument for carelessness in the subsequent handling of the cord, for it may be infected at any time.

What are the essentials for the growth of organisms? (1) the presence of the germs, (2) proper degree of temperature, (3) a suitable culture medium and environs, and (4) the presence of moisture.

It is evident that it will be very difficult to eliminate entirely the presence of bacteria, but we can avoid contaminating the parts with germs and we can assist in their removal by the use of aseptic and antiseptic measures. The body heat furnishes the proper temperature and, of course, cannot be interfered with.

The devitalized tissue of the cord forms a fine medium for the growth and development of the organisms. This can be removed by ligating or clamping the cord close to the skin margin. It has been pretty well demonstrated that better results are obtained by leaving as little cord as possible. Doubtless the methods of amputation proposed by Dickinson, which in his hands have given almost ideal results, accomplish this most thoroughly.

The presence of moisture may be controlled by having a small stump of cord and keeping it under conditions which favor rapid drying. Various experiments have been conducted along this line and it has been found that exposure to air is one of the best means of accomplishing this end. Hygroscopic powders have been used with some success—good results have been obtained by the use of astringent and inert powders. Equally good, or better results have been obtained without any dusting powder. Oily dressings have not given as good results. Dry occlusive dressings have been used. Gauze seems to permit of better and more rapid mummification than cotton.

In order to fulfil these conditions, the new-born babies have been treated as follows at the University of Minnesota Hospital:

After cessation of pulsation, the cords were clamped near the skin margin, the surrounding skin and cord cleansed with alcohol, and the clamp removed, to be replaced by a ligature in the groove made by the clamp. The end of the cord and the surrounding skin were painted with one-half strength tincture of iodin in some cases and in others left untreated. A sterile gauze dressing was then tied over the end of the cord. The babies were oiled for three days, then washed, but no tub baths were given until the navel was healed. Each day the stump and surrounding skin was washed with alcohol and the dressing changed when necessary.

A study of the clinical courses of these cases subsequent to delivery may be of interest and profit.

First in order is a consideration of those cases from which cultures were taken. In all there were sixty-five cases, one of these was a still-birth, there were three unsatisfactory cultures, which leaves sixty-one for study.

There were seventeen cases which showed no growth; of these four, or 23.5 per cent., showed a febrile reaction of over 100 F; there was one case with jaundice and the average maximum weight loss was 209 gm.

---

[6] Lambert: Umbilical Sepsis in the New-Born Occurring at the Nursery and Child's Hospital, New York, during 1896, Med. News, New York, 1897, lxx, 557. Petermöller: Neue Beiträge zur Behandlung des Nabelschnurrestes der Neugeborenen, Monatschr. f. Geburtsh. u. Gynäk., 1911, xxxiv, 207.

[7] Dickinson: Is a Sloughing Process at the Child's Navel Consistent with Asepsis in Childbed? Am. Jour. Obst., 1899. xl, 389.

[8] Cholmogoroff: Die Mikroorganismen des Nabelschnurrestes Ref., Jahrb. f. Kinderh., 1890, xxxi, 145.

Of the thirty-two cases from which non-pathogenic organisms were recovered, there were eight, or 25 per cent., with febrile reaction; three infants were jaundiced and the average maximum loss of weight was 188 gm.

There was a temperature rise in three, or 25 per cent., of the twelve cases in which pathogenic organisms were found; one was jaundiced and the average maximum weight loss was 202 gm.

The figures are so close for the different groups that the only conclusion one could draw would be that so far as this series is concerned it made little difference whether or not the organisms were present at birth.

There was no definite evidence of any serious infection of the navel. Two were somewhat reddened without any febrile reaction, jaundice or marked loss of weight. There were two with some foul odor, one had a febrile reaction of 102 F. and a weight loss of 340 gm. The other had no reaction. Neither had any jaundice. A number of others did not heal so rapidly as usual but showed no signs of infection. None of these babies died and all left the hospital in good condition.

Fifty-eight infants were treated as outlined above with alcohol and dry dressing. Of these, fourteen, or 24.13 per cent., had a rise in temperature to 100 F. or over; eight, or 13.08 per cent., were jaundiced, and of these four had fever and there was an average maximum loss of weight of 246.2 gm. The average loss of weight in the febrile cases was 314 gm. Five, or 8.6 per cent., had slight local evidence of navel infection, but none of them had a temperature rise to 100 F. The cord came off in five and one-half days on an average.

In the second series of cases, tincture of iodin was used to paint the cord and surrounding skin. Otherwise the treatment was the same as in the preceding series.

There were 186 babies treated in this way. The temperature rose to 100 F. or above in forty-two, or 22.58 per cent. of these; fifteen, or 8 per cent., were jaundiced, of which five had a febrile reaction. The average loss of weight was 228.05 gm. In the cases with fever, this loss amounted to 285.19 gm. Ten, or 5.37 per cent., had slight local evidence of infection of the navel, only three of which had any fever. The cord came off in seven and one-half days on an average. None of the babies in either series had any evidence of serious or fatal infection originating in the navel. How many of these febrile cases were caused by absorption of some toxic substance or the entrance of organisms through the umbilicus it is not possible to state. Many conclusions cannot be drawn from this rather small amount of material.

It is evident that some facts can be stated.

1. The cord is contaminated with pathogenic or non-pathogenic organisms at or immediately after birth in a large percentage of cases.

2. It is possible quite effectively to combat serious umbilical infections by comparatively simple methods; as shown by this report of over 200 cases with no mortality from this cause.

3. There seems to be little choice between the two methods used in these cases.

4. Jaundice in the new-born child is frequently associated with fever. It would not be illogical to suspect that this might originate by some agent introduced through the umbilical vein or lymphatics.

5. Febrile reactions are common in the new-born infant and are associated with other disturbances, such as a high primary weight loss and jaundice. They are due, no doubt, to many causes, but we, as obstetricians, should see that those due to infections entering at the umbilicus are reduced to an irreducible minimum.

For assistance in this work I am greatly indebted to the interns and nurses at the University Hospital, and especially to Prof. W. P. Larson for guidance in identifying the various organisms which were found.

ABSTRACT OF DISCUSSION

Dr. Charles S. Bacon, Chicago: I have made a practice for years of ligating the cord immediately after birth just at the juncture of the skin and cord, leaving a button simply large enough to prevent the sliding of the cord, and then dressing this with sterile cotton after first washing with alcohol. Every day I wash with alcohol and reapply sterile cotton. I have not forbidden the bath of the baby, believing that the amount of contamination in the bath-water is slight and is counteracted entirely by the immediate use of alcohol, which is the only safe antiseptic to use on the baby. With this method of treatment I have seen no serious infections and very rarely any infection at all. That there is a good deal of danger from the cord I have no doubt. I have myself seen a case of tetanus in midwife practice in which the bacillus was found around the navel. I believe that these observations can be extended to a variety of conditions, which will settle for us whether or not the bath is really accompanied with danger provided a safe antiseptic like alcohol is used immediately.

Dr. N. Sproat Heaney, Chicago: I consider the clamp that Dr. Adair mentions a good thing since it squeezes out the moisture and allows the cord to dry out early. The earlier that the cord drops off and the wound heals the better, so the best treatment of the cord is that which best promotes this and at the same time best protects it from infection. I believe that cutting the cord long is better than cutting it short. When the cord is cut short the invagination of the umbilicus draws the stump in, and it becomes so closely approximated to the child's abdomen that it stays moist unduly long and does not drop off early. If cut longer and at the time squeezed dry, the long dry cord, wrapped in the sterile gauze abdominal band, allows the air to dry out along the whole extent of the cord and the cord consequently drops off earlier. This was our experience in Vienna with the short and long cutting of the cord. Cotton is especially objectionable since it is too impervious to the air. I should not want a laparotomy wound manipulated daily, and for the same reason I should not want the child's cord to be manipulated daily. I should want it made as nearly sterile as possible at the time of birth and left untouched as much as possible thereafter, having dressings changed only when wet or soiled.

Dr. F. L. Adair, Minneapolis: In no branch of surgical work is asepsis more essential than in obstetrics, and I think further that we forget, many times, that we should carry our asepsis beyond the delivery of the mother and apply it to the baby also. In answer to Dr. Heaney, who said that the long cord drops off earlier than the short, I wish to say that this may not be desirable if we have a healthy wound covered with a scab. There is no better protection for the granulation tissue under the dry cord than a dry scab which covers it. Therefore, the statement that the long cord drops off early may not indicate a desirable condition.

Birth-and-Death Bookkeeping.—We need, first of all, to do what Sweden has done for 150 years, namely, to keep proper vital statistics. Vital statistics are the bookkeeping of health, and we cannot economize health any more successfully than we can economize money unless we keep books.—Irving Fisher, Ph.D., Professor of Political Economy, Yale University.

OPERATIVE TREATMENT OF CANCER OF THE STOMACH *

WILLIAM J. MAYO, M.D.
ROCHESTER, MINN.

The surgical treatment of cancer of the stomach compares favorably in results with the treatment of cancer of any other organ in the human body. When it is taken into consideration that nearly one-third of all cancers occur in the stomach and that their early discovery is a necessary factor in the cure of the disease, the necessity for a clear conception of the value of the various signs and symptoms is at once manifest.

With the hope of obtaining some definite information on these important points, an investigation was made in our clinic of the histories of a thousand patients submitted to operation for cancer of the stomach. These operations were performed between Jan. 1, 1894, and Dec. 31, 1912. For purposes of study they have been classified as follows: resections, 378; palliative operations, 246; explorations, 376.

The diagnosis of cancer of the stomach cannot often be made early enough to obtain a radical cure by operation, but a diagnosis of some condition of a surgical nature, probably cancer, can be made in time to permit operative interference in more than one-third of all cases (378 out of 1,000). The early diagnosis does not depend on any sign or symptom due to the cancer itself, but on the mechanical conditions produced by the growth. Therefore, in cases of suspected cancer of the stomach the recognition of such mechanical conditions should be the first aim of the diagnostician.

A probable diagnosis can be established by simple methods. In 67 per cent. of the total number of cases in this series tumors, some of which were of considerable size, could be palpated. The idea prevalent in the past that finding a tumor indicated an inoperable condition has been proved a mistaken assumption. A movable tumor is a favorable condition, especially if accompanied by early obstruction. We have a number of cases on record of patients who were operated on after a tumor was discovered, who are alive and well after a number of years.

Food remnants in definite amounts were found in 53.3 per cent. of the series, and gross obstruction was present in 20 per cent. Since more than 50 per cent. of all patients with cancer of the stomach have food remnants, it will readily be seen that, next to tumors, food remnants are the most important sign, not necessarily of cancer of the stomach, but of mechanical obstruction. A combination of tumor and obstruction is nearly pathognomonic of cancer in every case otherwise suspicious, and these two easily obtainable signs are of the first importance. Tumors, if present, are usually palpable and obstructive. At least 75 per cent. of cancers of the stomach have their origin in the pyloric end, a situation in which diagnostic conditions develop early. In this connection loss of weight is an important sign; the average loss in this series was 30 pounds.

Cancers of the body and fundus of the stomach occur in about 25 per cent. of all cases. When located at the cardia these growths produce early obstruction, but are not as yet surgically removable. In the body of the stomach but few can be diagnosticated sufficiently early to permit operation, because they are situated behind the margins of the ribs where a tumor cannot be palpated until a late stage, and, because of the wide gastric lumen, obstruction is a late development. In the few cases we have been able to diagnosticate early enough to warrant operation the patients were thin and gastroptosis was present, which made a tumor palpable.

The evidence furnished by the Roentgen ray is next in importance to the discovery of tumor and food remnants. It is a valuable aid in the diagnosis, not because it demonstrates in the early stage that cancer is present, but because it shows deformities and muscular deficiencies that are evidences of cancer. It is also of great importance as a means of elminating from the operative group those advanced tumors of the body and fundus of the stomach which lie concealed under the ribs, and which have already progressed beyond the reach of surgical aid. The Roentgen ray also gives valuable confirmation as regards the presence of obstruction and tumor in cases of cancer of the pyloric end of the stomach.

The examination of the contents of the stomach during the curable period of the disease is of relative value, but is not pathognomonic.

For purposes of comparison, an investigation has been made in our clinic of a thousand cases of ulcer of the stomach and duodenum in which operation has been performed within the last six years (from Jan. 1, 1907, to Dec. 31, 1912). There was an average total acidity in these cases of above 63, more than five-sixths of which was free. In the thousand cases of cancer of the stomach, there was an average total acidity of 31, about one-third of which was free. These data bear out the accepted hypothesis that low acidity and especially low free hydrochloric acid content is indicative of cancer of the stomach. Low acidity, however, may be found in a large variety of conditions, but one fact was noted particularly, that is, a cancerous stomach always contained some acid although the free hydrochloric was often absent. The more advanced the case the lower the acidity and the less the free acid content. Lactic acid was found in 43 per cent.

Blood in some form was found in 73 per cent. of the cases. Severe hemorrhage from the mouth occurred in 4 per cent., coffee-ground vomit in 6.25 per cent., and hemorrhage from the bowel in 9 per cent. Occult blood in the stool was the rule. Occult blood is present, however, in so many conditions other than cancer of the stomach that its value as a positive sign is not great. Smithies[1] states that the Oppler-Boas bacillus was demonstrated in 93.8 per cent. of the last 146 cases of gastric cancer observed in our clinic. These figures were obtained by oil immersion of smears stained by the colored agar method.[2]

The gastroscope has not yet been perfected for practical use, although a great deal of experimental work has been done with the instrument (Jackson,[3] Plummer,[4] Janeway[5] and others) which promises well for the future.

A history of gastric disturbance precedes cancer in a large number, if not the majority, of cases. The average duration of symptoms in the series of one thou-

sand cases was more than two years. This would indicate that in at least the majority of cases of cancer of the stomach, some lesion, ulcerous or otherwise, existed previous to the development of cancer —a point which has been disputed so far as cancer of the stomach is concerned, although accepted for all cancers on the surface of the body, where, so far as we know, cancer has never developed without a previous lesion. In an investigation by Wilson and MacCarty[6] of 218 cancers of the stomach removed by operation in our clinic, it was found that ulcer or some primary lesion of a similar character had existed in more than 50 per cent.

The art of the diagnostician lies in weighing the evidence at hand, and it is the rule that a correct diagnosis, if made at all, will be made on comparatively few signs and symptoms of definite value. The presence of tumor and obstruction, supplemented by roentgenoscopy and the examination of the contents of the stomach indicates the lines of investigation. The exploratory incision is the final test and on the diagnostician devolves the difficult task of determining which of the patients shall submit to such procedures. To give the patient a fair chance exploration must be done early.

Under present conditions the patient who is submitted to exploration with a probable diagnosis of cancer of the stomach has a little over one chance in three of a radical operation, a little less than one chance in three of a palliative operation and about one chance in three that the operation will be merely an exploration.

Every operation for cancer of the stomach should begin as an exploration. Exploratory operations for cancer of the stomach are not devoid of danger to the patient. In the 376 explorations in our series of one thousand in which nothing further was done, there were six (1.6 per cent.) deaths. In none of these cases, however, could the exploration be considered the direct cause of death. In most of the fatalities the disease was far advanced, a fact that we had failed to estimate correctly.

In cases of suspected cancer of the stomach it is the practice in our clinic to make a small incision

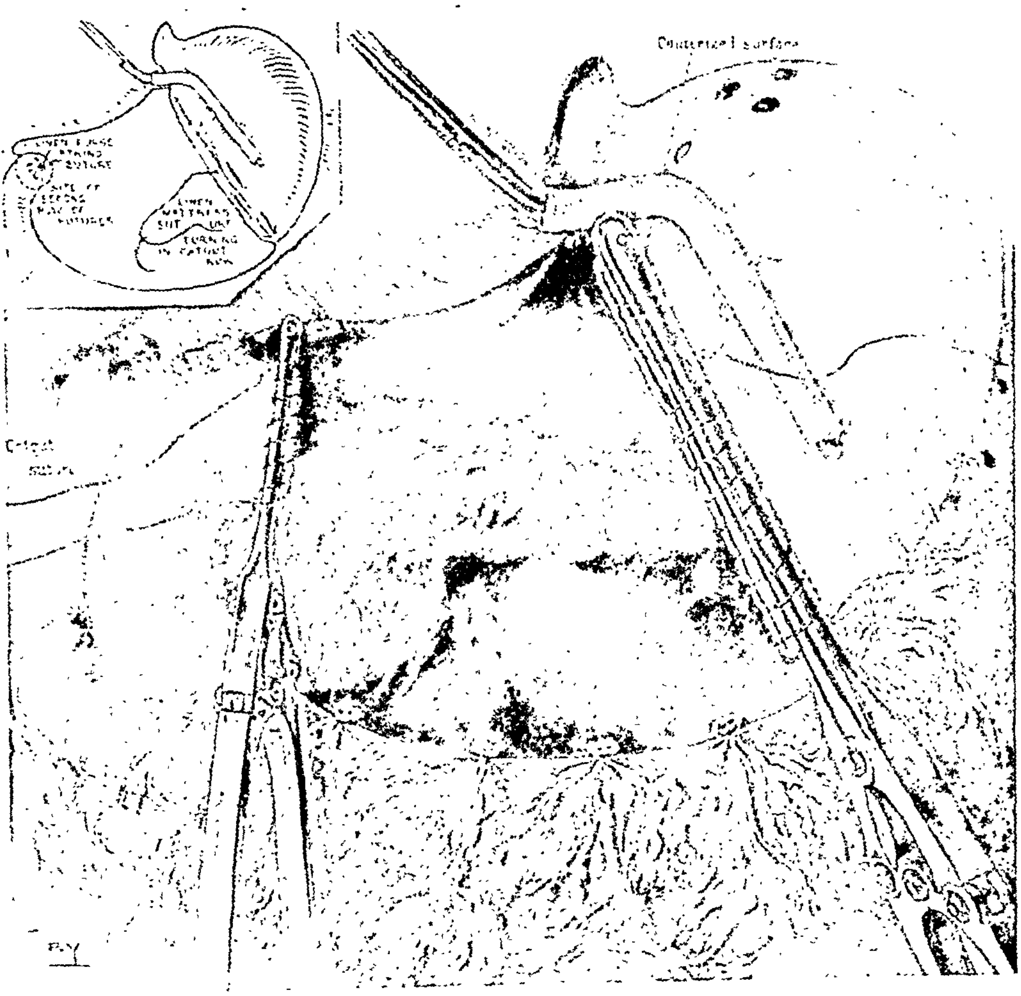

Fig. 3.—Method of closure of the ends of stomach and duodenum by continuous chromic catgut suture, to be followed by musculoperitoneal suture or linen (see small diagram).

in the epigastric midline, opening the peritoneum to the left of the suspensory ligament of the liver. The stomach and accessible portions of the liver are examined with two fingers. In a certain percentage of cases the hopeless nature of the condition will immediately be seen and the wound can be closed at once with buried sutures of linen or silk. This enables the patient soon to return to his family and friends. An exploration of this nature can be conducted under local anesthesia with novocain and the patient disturbed but little. In a large number of cases, however, such explorations are inadequate and the incision must be enlarged sufficiently to introduce the hand in order to make a more careful survey of the stomach, omenta, liver and peritoneal cavity. In such explorations the traction on the wound will ordinarily cause enough pain to make the use of ether advisable.

If, on exploration, a resection is deemed possible, the portion of the stomach containing the tumor is withdrawn from the abdominal cavity for further inspection. This examination will include the transverse colon and mesocolon. Occasionally the transverse mesocolon is involved in the arcade between the main branches of the middle colic vessels, and the portion involved can be removed without endangering the vascular integrity of the transverse colon. In a few instances in cases otherwise favorable for operation, the transverse colon was also involved and we then resected the diseased portion of the stomach with the involved transverse colon attached. One question rather difficult to decide is, what action to take when the disease in the stomach is mechanically removable, but infected lymph-nodes exist which are not removable. If such patients are in fair condition and the operation can be done without too great risk, we perform a resection. The resulting one or two years of comfortable existence for the patient seems to justify the action.

Moderate involvement of the pancreas does not necessarily preclude operation. Involvement of the pancreas has been considered a bar to resection of the stomach, but we have satisfactorily removed superficial portions of the pancreas in over 8 per cent. of our resections,

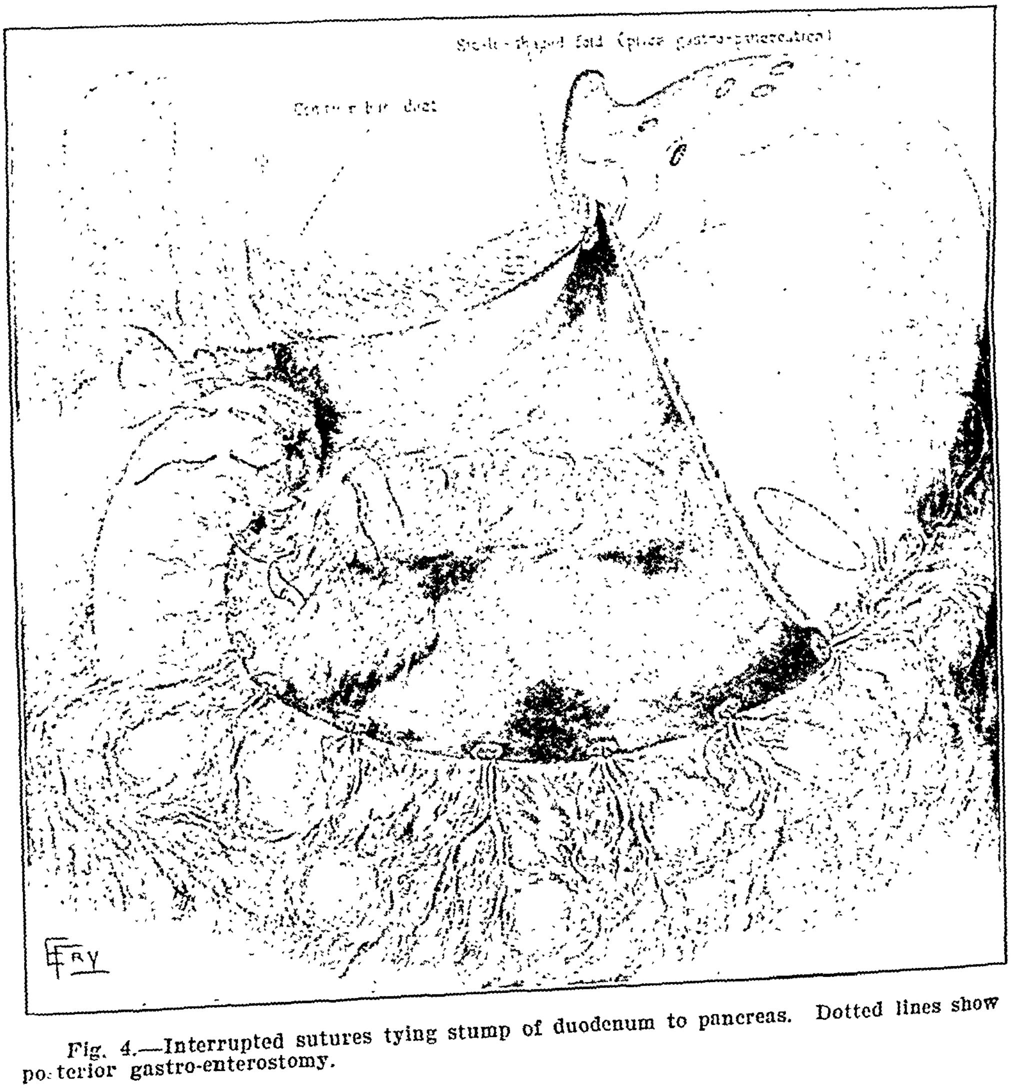

Fig. 4.—Interrupted sutures tying stump of duodenum to pancreas. Dotted lines show posterior gastro-enterostomy.

closing the end of the duodenum with purse-string sutures and implanting it into the excavation in the pancreas (Meyer[7]). Leakage has not occurred from either the pancreas or the duodenum, and altogether the technic has been most satisfactory. In our earlier work we were much concerned over the possible outcome of these procedures, since Haberkant[8] and Mikulicz[9] had shown a mortality of 70 per cent. or more in like cases. In reviewing our cases, however, we have not found that the mortality was increased more than 1 per cent. as a result of these complications.

Enlarged lymph-nodes will be found in a high percentage of cases of cancer of the stomach, but are not always malignant. The relative degree of involvement may be noted as follows:[10] (1) the group along the lesser curvature; (2) the inferior pyloric group; (3) the group along the greater curvature, and (4) the superior pyloric group. Early ligation of the four blood-vessels acts as a starting point for the separation of the lymph-nodes.

With some exceptions the restoration of the gastro-intestinal tract can be best affected by the Billroth No. 2 method, that is, complete closure of the ends of the duodenum and stomach with an independent gastrojejunostomy, preferably by the posterior route. If the remaining pouch of the stomach be small, however, anterior gastro-enterostomy appears to answer the purpose equally well and is easier of performance.

In some cases of extreme malnutrition it may be advisable to do a gastrojejunostomy to be followed by a resection in two or three weeks, when the patient is in better condition. We have practiced this method occasionally, but, if the case is otherwise favorable, we prefer to make an immediate resection because it disposes of a foul, sloughing mass in the stomach, and the risk in doing the complete primary operation is little, if any, greater than in doing the operation in two stages. Palliative operations on the stomach are of some value but they should not be performed except for the relief of mechanical conditions, such as obstruction or, occasionally, when a differential diagnosis between ulcer and cancer cannot be established. In an occasional case perforation of an ulcer with adequate peritoneal protection occurs, but whether it is benign or malignant cannot be determined. If malignant, it cannot be removed, and the operation will be palliative; if benign, a cure results.

Gastrostomy is often a valuable operation in cancer obstructing the cardiac end of the stomach. It should be made with a No. 16 English catheter and preferably by the Witzel method. We performed this operation in a number of instances with a small catheter, about No. 8 or No. 9 English, fearing leakage, but we have gradually acquired confidence in the use of the larger size, which permits greater range of dietary. Pierce Gould[11] has called especial attention to the value of a No. 18 English catheter is gastrostomy.

In pyloric obstruction an anterior gastrojejunostomy after the method of Wölfler[12] and Hartmann[13] is the operation of choice since it can be accomplished with less manipulation than is necessary to reach the posterior wall of the stomach in order to perform the posterior operation. In our experience a vicious circle has not followed this plan, and the average mortality has been a little more than 4 per cent. We have had a somewhat higher mortality following the posterior gastrojejunostomy for malignant disease, evidently due to the increased manipulation.

Jejunostomy is occasionally a valuable method in cases of cancer of the stomach, especially in those high posterior perforations in which a radical operation is not possible. The involvement may be so high on the stomach that a gastrojejunostomy cannot be done on the proximal side, and in some cases it cannot even be determined whether or not the ulcer is benign or malignant. The jejunostomy is usually made from about 12 to 16 inches down from the origin of the jejunum by the Witzel method and using a No. 12 English catheter. We have had no leakage in these cases, nor has the attachment of the jejunum to the abdominal wall been a cause of later trouble. Jejunostomy, in cases of either ulcer or cancer, affords adequate feeding and gives complete rest to the involved stomach. If the condition be ulcer, the improvement in nutrition is almost as valuable as rest in stimulating the healing process. A rapid gain in weight and strength is the rule in these cases. The operation is also of great value in cases of accidental injury during the exploration of a cancerous stomach in which resection cannot be done.

CONCLUSION

It may be said that with our present means of diagnosis, cancer of the pyloric end of the stomach can be recognized sufficiently early to perform the radical operation in at least half the cases. The mortality is about 10 per cent., depending largely on the class of cases accepted for operation. If an early diagnosis has been made and the patient is in good condition, the mortality will be less than 5 per cent. There is a prospect of a five-year cure in about 25 per cent., and of a three-year cure in 38 per cent., in the case of those who recover from the operation. Comparatively few patients who recover following resection fail to get more than one year of relief.

ABSTRACT OF DISCUSSION

Dr. William L. Rodman, Philadelphia: There are forty thousand deaths from cancer in the United States every year, and, if we accept the statement of that conservative pathologist, Virchow, even a larger percentage than Dr. Mayo gave to-day, 35 per cent., die from cancer of the stomach.

There are several points which, I think, ought to be made clear in connection with cancer of the stomach. It is frequently impossible to make a positive diagnosis at such time as to warrant a radical operation from symptoms alone, but nearly always there will be enough symptoms to warrant an exploratory operation. My judgment is that in a disease which is so common and so fatal, and which so quickly passes the operable stage, more frequent exploratory laparotomies are necessary and should be demanded. The symptoms of cancer are vague, indefinite and widely variant, depending much on its location. At the cardia they may be pronounced early; at the pylorus, the more usual site, they are usually late and due to obstruction. The surgeon should, moreover, be held accountable for the proper surgical procedure. Palliative operations are of questionable utility. Encouraging as it is to have Dr. Mayo tell us that in 38 per cent. of his operations there has been a three-years' cure and in 25 per cent. a five-years' cure, could we not do a great deal better if we operated during the precancerous stage or when the lesion is still benign, or simple ulcer? Not only do we find cancer engrafted on ulcer in more than 50 per cent. of the cases at the Rochester clinic, but Mayo Robson finds it also in 59 per cent. of his cases, Moynihan in 72 per cent. and a Russian authority, Shaperko, in 90 per cent. Many of the French surgeons assert that every case of cancer is necessarily preceded by ulcer. Why is it not better, therefore, to excise all ulcers of the stomach, or at least those which are hard and callous and situated in the pyloric region and which constitute about 80 per cent. of cancers of the stomach. We cannot escape the conclusion that there must be a close etiologic connection between benign and malignant ulceration of the stomach, and that the time to cure cancer is when it is still a simple ulcer. This can be done with a very small mortality. I believe, and have believed for many years, that we shall live to see the time when all ulcers that are not bound down by prohibitive adhesions to the pancreas, gall-bladder, the large intestine, etc., will be promptly excised. I have followed this practice for the last thirteen years.

Dr. John B. Deaver. *Philadelphia:* As Dr. Mayo's statistics show, cancer of the stomach is a curable disease if taken in the curable stage. Dr. Mayo has shown that there is practically no mortality (0.6 of 1 per cent.) in an exploratory operation. This is a strong argument and one that should appeal to us. To perform an exploratory operation is practically taking no risk at all and, as Dr. Mayo also said, it is the final test. I was glad to hear Dr. Mayo's statement that roentgenoscopy has been of service in aiding early diagnosis and in showing the extent of the disease in certain cases.

Dr. John A. Lyons, *Chicago:* I wish to add to the dis-ssion this much: I sent a friend of mine to Rochester about o months ago for the removal of a cancer. The abdomen s opened, and it was discovered by Dr. Mayo that there was no cancer, but an ulcerated condition of the stomach. Dr. Mayo informed my friend that in six weeks he would be as well as ever. Cancer of the stomach had been the diagnosis of several surgeons in Chicago. The patient of whom I speak had lost 46 pounds and he is well to-day and has a fair prospect of living many years.

Dr. W. J. Mayo. *Rochester, Minn.:* I think we all occasionally make the mistake in certain cases of treating as ulcer a lesion which afterward proves to be cancer. It is difficult to determine, by the ordinary methods of diagnosis during operation, whether a certain gastric ulcer is benign or malignant. Unless we can procure a piece of tissue for diagnosis we must be guarded in our statements. The opposite mistake also occurs. In our clinic several patients on whom palliative operations were done for supposed hopeless gastric cancer remained well for more than five years. The operations were done for the relief of obstruction. We cannot, therefore, blame the medical man for not always making a diagnosis of cancer of the stomach, as he must employ indirect methods when we sometimes fail with direct ones. In the examination of these patients one should keep at least four things in mind: First, is there a tumor and is it movable? Repeated examinations should be made if in doubt; second, food remnants in the gastric content; third, Roentgen-ray bismuth photographs; fourth, examination of test-meal, etc.

EXPERIMENTAL TRANSPLANTATION OF INTESTINE AFTER EXTENSIVE EXCISION OF THE SIGMOID [*]

J. SHELTON HORSLEY, M.D.
RICHMOND, VA.

This subject was suggested to me by a case that came under my care about five years ago. The patient was a colored man, a deaf mute, who had been suffering from obstruction of the bowels for several days before admission to the hospital. He was enormously distended and his condition was desperate. Operation was done under cocain and a volvulus of the sigmoid found. The sigmoid was twisted and so distended that it resembled a large cyst. The volvulus was excised and after removing the diseased bowel it was impossible to approximate the lower end of the large intestine to the small portion of the descending colon that was left. An artificial anus was formed. The patient recovered and left the hospital about four weeks after the operation. He was very ignorant and could not properly take care of himself. His condition was pitiful in the extreme.

The necessity for excision of the sigmoid occurs not infrequently. Sometimes it should be so extensive that the ends of the bowel cannot be united. The chief conditions that render this necessary are volvulus, ulcers, or malignant tumors. The sigmoid may be secondarily involved by growths of the ovary or uterus so that its excision is necessary either from extension of the growth or from interference with the nutrition of the sigmoid. Sometimes it is so entangled in inflammatory products, or affected by benign ulcers, tuberculous or dysenteric, that extensive excision is advisable. In a few cases of dysentery in which absolute rest is indicated for the ascending and transverse colon and excision demanded for the sigmoid, an operation which would accomplish this and at the same time do away with the necessity of an artificial anus would be desirable.

Bearing these points in mind, I have been working experimentally on the problem. All the experiments have been done on dogs and the operations have been performed under full ether anesthesia. Every precaution was taken to prevent pain and suffering to the animal, and no more experiments were done than seemed necessary to prove the point in question.

In the first experiment, part of the sigmoid was excised and a section of the ileum four and a half inches long was transplanted. According to some previous experiments[1] it seems proved that if as much as 4½ inches of the small intestine be devascularized entirely and the omentum wrapped around it, nutrition will be maintained. So this amount of the ileum was removed and transplanted where a portion of the sigmoid had been excised. The segment was surrounded by omentum which was held in position by a few silk sutures. The dog died in twenty-four hours, and postmortem showed that the transplanted segment was completely gaugrenous. The technic was then varied so that about four inches of the ileum was resected leaving its mesentery attached. The ileum was reunited and its resected portion transplanted to take the place of the excised sigmoid. After the suturing was done, the mesentery of the transplanted section of the ileum was cut and the segment surrounded by omentum. The dog lived nine days. Postmortem showed that while most of the transplanted bowel had lived there were perforations in several places and general peritonitis. The ileum was next transplanted in the manner just indicated except that its attached mesentery was left intact. About 2 inches of ileum were transplanted. This dog died in four days and the condition of the intestine was quite similar to that found in the second experiment.

From these experiments it seemed that the transplantation of a segment of small intestine to take the place of a defect in the sigmoid was not satisfactory because the ileum, being smaller in diameter than the sigmoid and not prepared to resist the impact of the hard, dry, fecal masses gave way under the new conditions, ulcerted and perforated. In order to overcome this, it would be necessary to deliver the fluid fecal contents directly into the distal end of the excised sigmoid. This was accomplished in nine experiments in the following manner: The ileum was cut across at the ileocecal valve and transplanted into the distal end left after excising the sigmoid. The end of the descending colon, or upper stump from the excised sigmoid, was then drained by a lateral anastomosis into the ileum. (Fig. 1.) The advantages of this operation are apparent. The fluid fecal contents are delivered directly into the lower stump of the sigmoid without any undue friction on the transplanted ileum. The remaining portion of the large bowel has its secretions drained into the ileum and at the same time acts as a reservoir. If the fecal current is delivered too rapidly, the bowel can hold some excess feces and so prevent the chronic diarrhea which is frequent and often serious after total excision of the large bowel. Excision of the cecum, ascending and transverse colon, or the necessity for draining them by an external opening is obviated by this operation. The procedure is comparatively simple—merely cutting across the ileum, transplanting it to the sigmoid end-to-end and then a lateral anastomosis of the end of the large bowel to the ileum higher up. This can be done quickly when compared with such prolonged operations as total excision of the large bowel, is less dangerous, and, on the other hand, does not require an artificial anus, or any secondary operation as would be the case if the large bowel were drained externally.

---

[*] Read in the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

[1] Horsley, J. S.: The Journal A. M. A., Aug. 12, 1912, p. 597; and Ann. Surg., April, 1913.

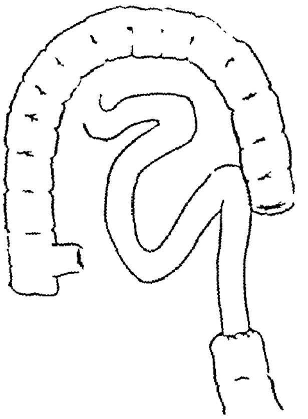

Fig. 1.—The sigmoid has been resected. The upper stump has been closed by invagination, the ileum cut across near the ileocecal valve, and its distal end closed by invagination. The ileum has been sutured to the distal portion of the sigmoid end-to-end and the descending colon is drained into the ileum by a lateral anastomosis. In this way, the defect left by excising the sigmoid is bridged over by transplanting the ileum, and the secretions from the large bowel are drained into the ileum.

Of the nine dogs operated on, six survived and were killed by chloroform, 84, 68, 48, 50, 47 and 54 days, respectively, after the operation. The openings were satisfactory and the intestine was well nourished in each case. Adhesions were always present though there was no evidence of obstruction. In one specimen there was a small abscess near the stump of the descending colon; this stump had been simply ligated without invagination. In two dogs of the series, the bowel ends were sutured and invaginated as described below; both the specimens were satisfactory though there were some adhesions. Of the three deaths, one occurred from perforation of the ileum just opposite the site of the lateral anastomosis by a large piece of bone sixty-one days after operation. The bone was jagged and caught in the lateral opening and was held firmly, a sharp spicule perforating the ileum. Both of the other fatal cases were due to leakage at the stump where simple ligature without invagination was used. One dog did not die till forty-three days after operation. An abscess had probably formed at the stump of the colon and been localized for some time before rupturing. Post-mortem showed leakage at the stump of the colon with general suppurative peritonitis. The third dog died two days after operation. Post-mortem showed leakage at the stumps of colon and ileum, and peritonitis

The steps of the operation in order are: excision of the sigmoid, closure of its proximal stump, division of the ileum about 2 inches from the ileocecal valve, closure of its distal stump, union of the ileum to the lower end of the sigmoid, and lateral anastomosis between the ileum and descending or transverse colon. The details of these steps are important and will be discussed fully. Let us first consider the technic of closing the bowel ends. This is done at the end of the descending colon and at the distal stump of the ileum. I first tried Lilienthal's method of simply ligating firmly the bowel ends just as in ligating the pedicle of a tumor. This is quick and simple and works nicely in appendectomy. In the experiments, it was found that two of the seven dogs in which the ends were merely ligated, died from leakage at the stump of either the ileum or colon. This seems due to the fact that although the ligatures may be tied tightly the muscular coat is so thick and heavy the ligature gradually cuts and becomes loose. The powerful peristalsis of the dog's bowel also tends to loosen the ligature. In the dog a simple ligature of the bowel end is unsafe. The method of closing the bowel ends that was found satisfactory was to place a stout overhand suture in the margins of bowel ends, going through both walls at the same time. No deeper bite should be taken than is necessary for a secure hold and the stitches should not be too close together. The ends of the suture are then tied tightly together, making only one knot. The ends of the suture may be caught with a hemostat and used to steady the bowel while inserting a purse-string suture, or the purse-string may be placed at what is thought to be the proper place before the bowel is divided. The purse-string suture should be placed not more than half an inch from the end of the bowel, for if placed farther away invagination is more difficult. After invagination of the bowel ends and tying the purse-string suture, the next step is the union of the ileum to the lower end of the sigmoid.

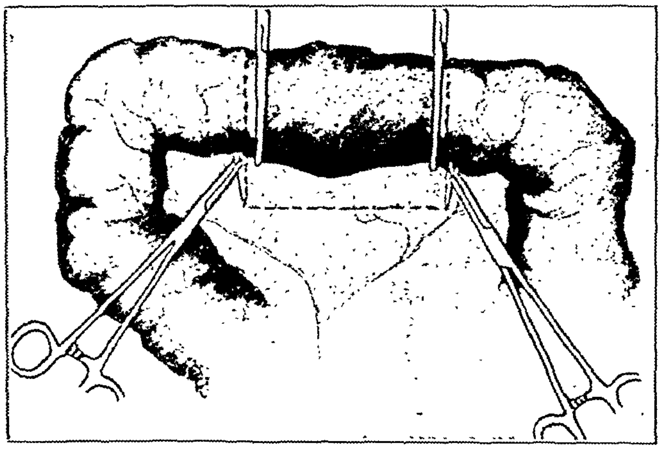

Fig. 2.—Before the bowel is divided, its mesentery is cut close to the bowel wall and the triangular space, caused by separation of the layers of the mesentery just before they cover the bowel, is clamped with a hemostat and ligated with silk or linen. This area is composed of areolar tissue rich in blood-vessels and lymphatics which absorb quickly, and even though it is closed off after it has been inoculated, the germs are merely sealed in and are likely to cause breaking down of the union at this point later on. The procedure indicated in the cut obviates this and also brings together the peritoneum at this point.

Because of the short end of the sigmoid that would be left after a wide excision, the union here is best done end-to-end, and not laterally. As fluid feces will be delivered by the ileum directly at the point of union, there seems no reason why the end-to-end union should not be made as in the small bowel, though for additional safety in man a rubber tube might be placed from the anus to the point of union and fastened in place for a few days by a catgut suture. The method of end-to-end union that has proved satisfactory in all these cases is one that I have been using for more than eight years. Before the bowel is divided, the mesentery is cut close to the bowel wall, and the triangular area where the mesentery separates is grasped with a hemostat and ligated with silk or linen (Fig. 2.) The objection chiefly urged against end-to-end union of bowel is that healing is difficult at the mesentery border and the cause of non-union is ascribed to lack of peritoneum. This may be true, but it is probable that infection of this area is also the cause of many failures. It is the usual practice to divide the bowel from the free border to the mesenteric border and the knife or scissors that cuts the septic mucosa also cuts through this triangular area, which is areolar tissue rich in blood-vessels and lymphatics. After this area is inoculated in this manner, it is the usual practice to close it, thereby sealing in bacteria that are likely to cause infection and non-union later at this point. By adopting the step mentioned above, this area is covered with peritoneum and, what is more important, its blood-vessels and lymphatics are closed before the septic bowel is opened. The bowel is then divided and its ends cleaned with moist antiseptic gauze. The first stitch begins in the end of the bowel at the operator's right-hand, about one-third of an inch from the mesenteric border. It is a mattress stitch and starts from the mucosa of the right bowel penetrating all coats. Then the needle is carried across to the left end of the bowel and penetrates all coats, entering on the peritoneal surface and emerging from the mucosa. It comes back in the reverse direction, entering the mucosa of the left bowel end and emerging on the peritoneal surface, then enters the peritoneal surface of the right bowel emerging from the mucosa. The thread is tied leaving an end about four inches long which is clamped with a light hemostatic forceps. The needle is then passed back and forth through all coats of the bowel, suturing away from the operator, making a continuous mattress stitch. Care must be taken to include a portion of the mesentery that has been tied, else it will slip back and will not be included in the suture. Each suture here must be very snugly approximated. After about one-third of the circumference of the bowel has been sutured, the needle emerges from the lumen of the right end of the bowel, and is thrust through all walls of the right end, appearing on the peritoneal surface (Fig. 3). The stitch is continued as a right-angle stitch penetrating all coats (Fig. 4). Snug approximation should be made with each stitch and at about every fourth stitch a back-stitch should be taken in order to prevent the thread from drawing too tightly and so diminishing unduly the caliber of the bowel. This is done by taking two stitches on the same side, the last one being slightly farther back than the preceding stitch. In this manner it is impossible to draw the thread too tightly. It is very important to have the first third of the suture line that unites the mesenteric border drawn tightly, but after this unless the back-stitch is taken at intervals, pulling the thread may diminish the lumen so much as to produce obstruction.

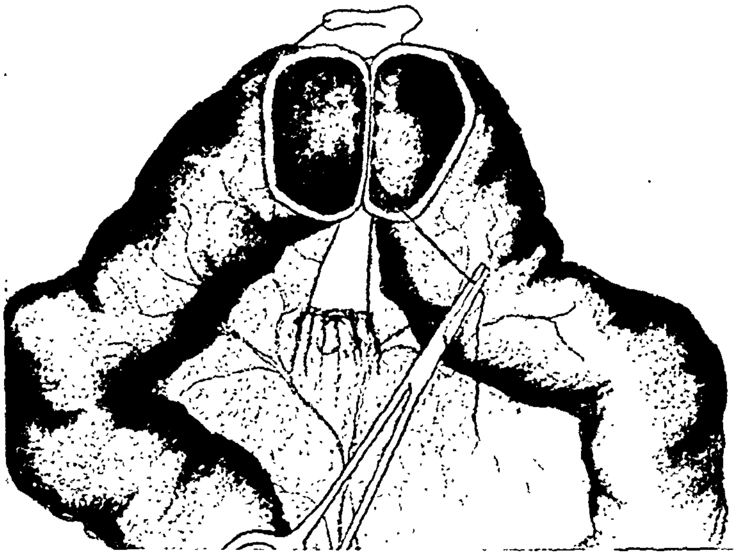

Fig. 3.—The first stitch starts in the end of the bowel at the operator's right hand about one-third of an inch from the mesenteric border. It is a mattress stitch and penetrates the wall of the right bowel from within out. The needle is then carried across to the left end of the bowel and penetrates all coats, entering on the peritoneal surface and emerging from the mucosa. It comes back in the reverse direction, entering the mucosa and emerging on the peritoneal surface, then enters on the peritoneal surface of the right bowel and emerges on the mucosa. The thread is tied, leaving an end about four inches long which is grasped in hemostatic forceps. The needle is then passed back and forth through all coats of the bowel, suturing away from the operator, and making a continuous mattress stitch. After about one-third of the circumference has been sutured, the needle emerges from the lumen of the right end of the bowel and is then thrust through all walls of the right end from within out, appearing on the peritoneal surface of the right end. The stitch is then continued as a right-angled suture penetrating all coats of the bowel.

The suture is continued toward the operator and is carried a short distance, about a stitch, beyond the lowest point where the original thread left when the knot was tied comes out. This last stitch should be taken in the left-hand side of the bowel. The thread is then tied firmly to the original end that is grasped in the hemostat. The knot should be tied parallel to the line of suturing so as to sink in easily and should be tied quite snugly. If a back-stitch has been taken at proper intervals, there is no danger of reducing the lumen by tying this knot too tightly. It had best be tied three times and then cut short; the ends will disappear within the bowel.

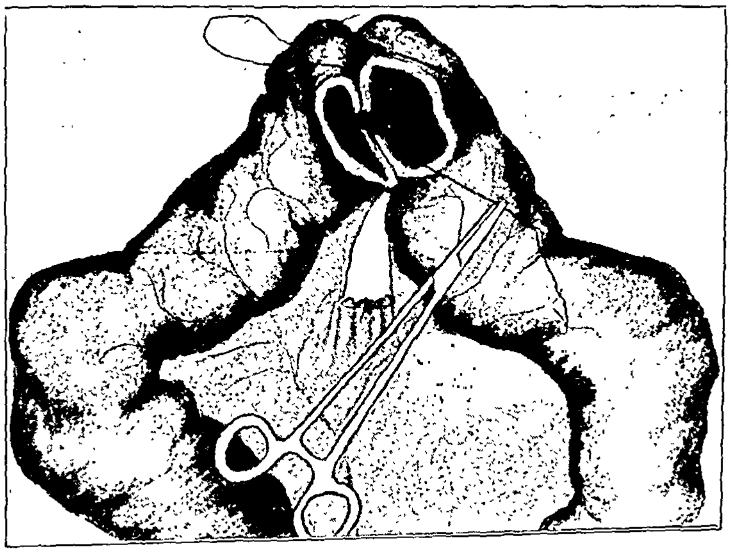

Fig. 4.—The suture is continued, inverting the bowel edge as it goes. A back-stitch should be taken at every fourth stitch. This is done by taking two stitches on the same side, the last one being slightly further back than the preceding stitch. This makes it impossible to draw the threads so tightly as to cause puckering and too great diminution of the lumen of the bowel.

This method is simple, leaves all knots within the bowel, and I have never seen a leakage from it when it was properly used. The danger of obstruction to the lumen is obviated by putting in occasional back-stitches and by properly approximating each stitch as it is made. The thread is all practically buried, leaving almost no thread exposed on the peritoneal surface, and the whole suturing can be done very quickly. All of these features are important and particularly so after a rather extensive operation such as transplantation of the bowel after resection of the sigmoid.

The next step to be considered is the draining of the large bowel. This is best done by a lateral anastomosis between the end of the descending colon and the ileum at such a point above its junction with the lower portion of the sigmoid as to provide against any undue tension. The lateral anastomosis can be used according to the technic of a gastro-enterostomy. A rubber-covered clamp is placed across the colon about four inches above its stump and another similar clamp grasps the ileum laterally. The union is made as close to the end of the colon as possible. After thoroughly packing off the surrounding structures, one stitch of silk or linen is taken at the upper portion of the proposed lines of incision into the intestines and the suture tied and left long. This fixes the ileum and colon together. An incision is then made into each and the bowel cleaned out with moist, antiseptic gauze. The bleeding points, if spurting, are clamped and tied taking a small bite of tissue. The bowel is united by a continuation of the first stitch which is applied quite snugly and each stitch locked as in the button-hole stitch. When the lower end of the incision is reached, the suture is converted into right-angled stitch penetrating all coats, and about every other stitch is locked after the manner of the button-hole stitch. The end is then tied to the original end which was left long and grasped with the forceps.

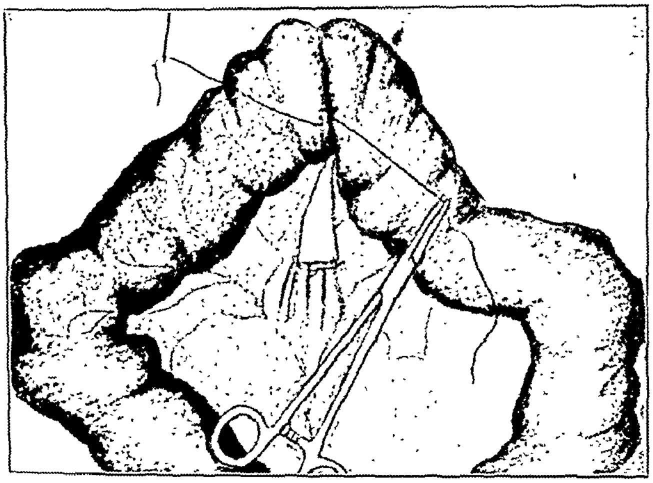

Fig. 5.—The suturing has been completed, the last stitch being taken in the left end of the bowel slightly beyond the lowest point where the original end of the thread comes out. The knot should be snug and should be tied parallel to the line of sutures so that it will sink in easily. The ends should be cut short and will sink into the lumen.

This suture has always been satisfactory, it is practically buried throughout its course, and it saves an apparently unnecessary second suture. It is done with a curved needle. One row seems all that is necessary here and makes less flattening of the bowel. If the operator prefers, however, there is no serious objection to following the identical technic of a gastro-enterostomy and using two rows of sutures.

ABSTRACT OF DISCUSSION

Dr. C. E. Ruth, Des Moines, Iowa: The function of the large intestine is to absorb a large portion of the solid matter. To overcome the difficulty which may be caused by the small intestine carrying the fecal current of the colon it may be necessary to make the anastomosis in the side of the colon. In intestinal anastomosis one point of danger is due to the divergence of the mesentery, and the next point of greatest weakness is that most distant, because of the lessened blood-supply. Another thing that should be kept in mind is that in the union of these two points with an angulation like that when the end-to-end anastomosis is made, there is not the slightest risk of contraction of the lumen of the intestine, but you can make the angle greater. The tendency is to a lesser degree of caliber rather than to a greater when an end-to-end anastomosis is made.

Dr. A. Goldspohn, Chicago: One feature in technic in favor of side-to-side anastomosis is that an aseptic field for work is preserved to the last moment, when the second intestinal lumen must be opened, because both ends of the bowel first cut in two have been turned in and closed. When the first bowel is severed with a cautery, however, as mentioned by Dr. Horsley, the same advantage can be secured for an end-to-side anastomosis by cutting off the eschar from the used end of the first bowel finally at the same time that the lateral incision is made into the second bowel involved—both being done after the posterior row of seroserous stitches has been placed. I had occasion to do this recently in an ileo-sigmoid anastomosis in a young woman who had an extreme elongation and descensus of the transverse colon, after three previous abdominal sections. The amount of digestive disorder (sometimes accompanied with much pain) experienced in that case for about eight weeks after this exclusion of the large bowel suggests careful deliberation before taking this step. The technic of circular enterorrhaphy—which Dr. Horsley describes and which he has published before, I have found to be practical and more simple than that of Dr. Connell.

Dr. J. S. Horsley, Richmond, Va.: It is true that some fecal matter accumulates in the large bowel, but not a large amount, and even that amount is to some extent obliterated by the constant flow of liquid feces. The part that does become hard is softened by the constant flow of liquid feces and peristalsis is carried on. The point is well taken. The description was merely diagrammatic.

THE HEALING PROCESS OF OSTEOSARCOMA UNDER THE INFLUENCE OF THE ROENTGEN RAYS [*]

GEORGE E. PFAHLER, M.D.
PHILADELPHIA

The healing process of osteosarcoma is very similar to that observed in the healing of any other bone disease, and consists of a bone sclerosis. This is indicated by a progressive deposit of lime salts in the tumor area. This process continues over a period of from several months to a year or more, and progresses long after the roentgenotherapy has been discontinued. The deposit of lime salts does not depend, therefore, on stimulation by the Roentgen rays, but is simply Nature's method of replacing the tumor tissue which has been destroyed by their action.

---

[*] Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

[*] The subject originally announced was "Good Results Obtained in the Treatment of Sarcoma," but I found that this subject would make my paper too long, so I have limited myself to this one group of sarcomas. Owing to lack of space this article is here abbreviated by the omission of four case reports which are included in the Transactions of the Section and the author's reprints.

It is well known that the rays cause a granular degeneration of tumor-cells before affecting the surrounding healthy tissue-cells, probably because of their lower degree of vitality or resistance. This effect is due to the chemical action of the rays absorbed, just as these rays show their chemical action on the silver salts on photographic plates, on the glass of a Roentgen-ray tube and on the lead-glass shields which are used around the Roentgen-ray tubes for protection. These chemical effects can be observed any day, in any Roentgen-ray laboratory. If such chemical changes will take place in inorganic materials, and especially in such a stable product as glass, on which most of our strongest chemicals have no effect, it is not strange that a most decided chemical effect should be observed in tumor-cells, which are organic and less well organized and therefore less stable than the healthy tissues of the body.

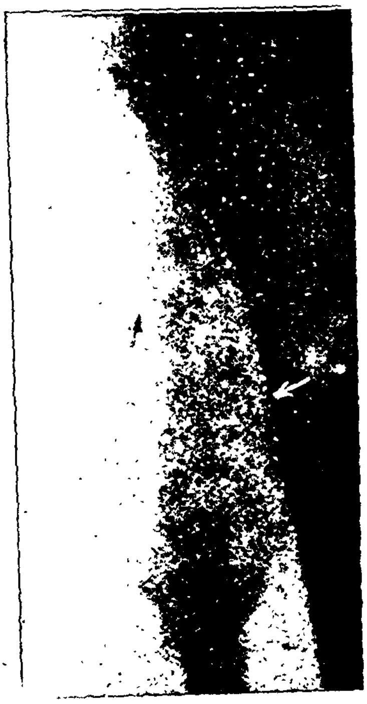

Fig. 1, Case 1.—Absence of lime salts in sarcoma area is shown. Dark arrow points to the area from which a section was removed March 3, 1906. (Plate reversed by printer.)

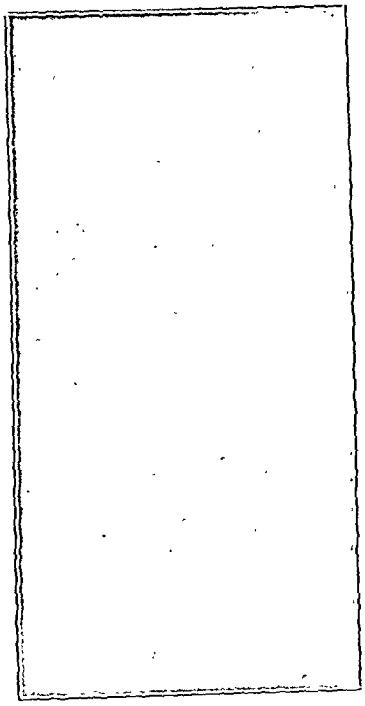

Fig. 2, Case 1.—Notice beginning calcification under the periosteum or periphery; also slight contraction of the tumor area at the end of a month (April 7, 1906).

The good effects of the Roentgen rays on sarcoma, according to my observations, have been more marked in osteosarcoma than in sarcoma involving other tissues of the body; and of the osteosarcomas, the medullary or central type responds best. Remarkable results, however, are often obtained in sarcoma of the soft tissues. When one realizes that all chemical and biologic effects of the rays depend almost entirely on those which are absorbed and not on those which pass through, it will not be surprising that the most marked effect should be observed in bone tumors, since it is a well-known fact that the bones absorb many times more rays than any other tissues of the body. This is seen clearly in every roentgenogram. In fact, the bones absorb all of the soft, and most of the hard, rays. Therefore, we can use rays that will easily pass through the soft tissues and in them produce little or no effect (because they are not absorbed), while a most marked effect will be produced on the bone tumor because they are absorbed. A secondary effect of the rays is that due to the secondary radiations, which is similar to that produced by the primary radiations. The quantity of secondary radiations given off from any element corresponds roughly to the density of the element. Therefore, since bone is more dense than any other tissue of the body, even the secondary radiations and their effect will be greater than in the soft tissues. I have discussed this phase of the subject because many might be surprised and incredulous, on account of the popular medical opinion that the rays are useful therapeutically only in superficial affections.

The diagnosis of osteosarcoma can be made, and the healing process can, fortunately, be beautifully observed by means of the Roentgen rays. This is especially true in the study of the long bones. The characteristic pathologic appearance of osteosarcoma is when briefly expressed, a decalcification without sclerosis, but associated with new growth. If the tumor is a central sarcoma of a long bone, it is seen to have destroyed the cancellous structure locally, and this appearance is gradually shaded into the healthy bone-tissue. The total diameter of the bone is likely to be increased, and, if advanced, the wall of the bone will be seen to have broken through and the soft tissues to have become involved. If it is a peripheral sarcoma, the tumor-tissue which early infiltrate the soft tissues will be seen to lift the periosteum in a spindle form, and may have infiltrated only the surface of the bone.

All of these cases that I have studied and treated belong to the central or mixed type. In the healing process there is a gradual increase in the amount of lime salts, and this deposit seems to proceed from the periosteum. When the treatment is successful, the entire tumor area becomes infiltrated with lime salts, until it is as dense as normal bone. The size of the tumor area is usually somewhat reduced, but I believe never returns to normal. In one case (No. 3) there seemed to be no reduction in the size of the tumor, but with the increase of lime salts in the tumor area the patient's symptoms disappeared.

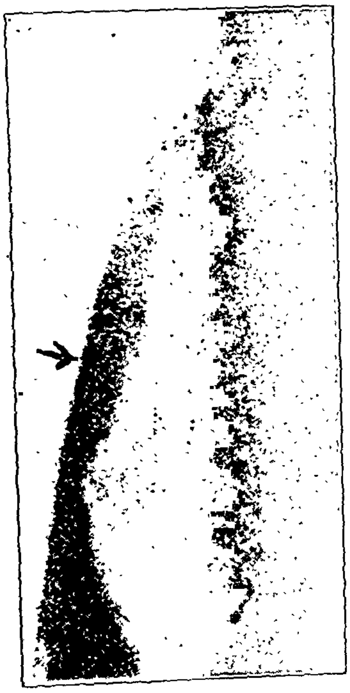

Fig. 3, Case 1.—Notice increase in the calcification at the end of the second month of treatment (May 3, 1906).

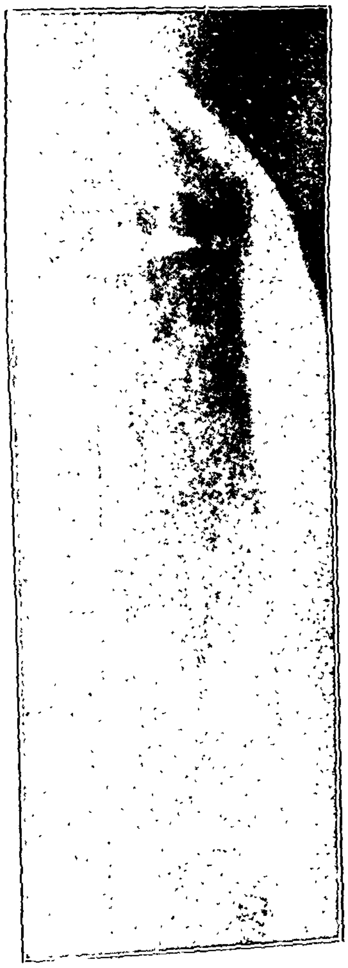

Fig. 4, Case 1.—Notice complete calcification at the end of six years (April 5, 1912). (Plate reversed by printer.)

The cancellous structure never attains a normal appearance, but presents a collection of lines without definite order. This sclerotic area is then more dense than normal bone. I have found that these areas continue to become more dense for a considerable time after the roentgenotherapy has been discontinued, but that they attain approximately normal density within a year.

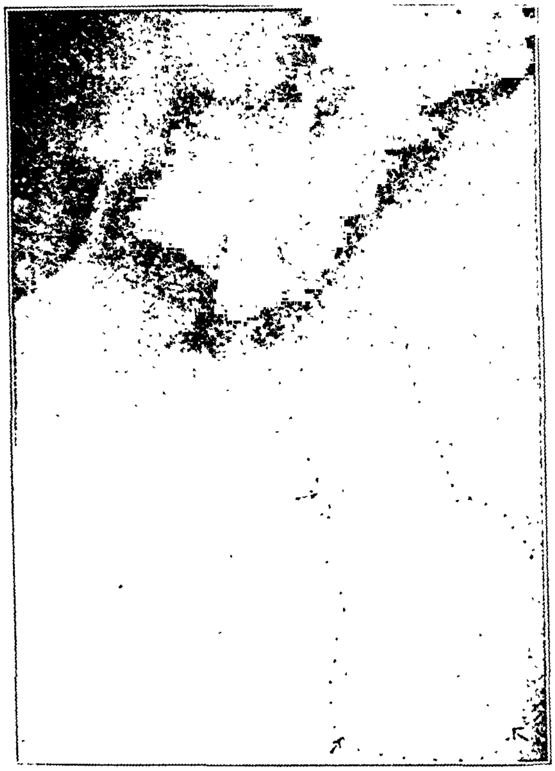

Fig. 5, Case 3.—Osteosarcoma of pubes and ischium. Shows the disease in the bone and the tumor extending 6 inches down the thigh, which is only slightly more dense than the soft tissues (Feb. 12, 1912).

It has been my privilege to study a number of cases of osteosarcoma by means of serial roentgenograms made during the course of treatment and from one to seven years afterward. These cases are reported not in the order of occurrence, but more particularly in the order in which they are most instructive, and chiefly with reference to the locality involved.

REPORT AND DISCUSSION OF CASES

CASE 1 (Figs. 1, 2, 3 and 4).—Miss L. B., aged 18, was referred to me by Dr. M. P. Warmuth, March 5, 1906. She had bruised the upper portion of the left leg ten months previously, and on this area a painful tumor developed. Feb. 20, 1906, a roentgenoscopy showed the upper 9 cm. of the fibula swollen to a diameter of 3 cm., or three times the diameter of the normal shaft of the bone. This diseased portion apparently contained no lime salts. It showed no medullary cavity, but in the upper portion could be seen a cavity about 1.5 by 1 cm., which was produced by the removal of a section for microscopic examination. Otherwise the tumor was uniform in consistency and showed only slightly more density than muscle. The diagnosis of osteosarcoma was made. Microscopic examination in the pathologic laboratory of the Medico-Chirurgical Hospital showed the tumor to be a round-cell sarcoma.

Amputation at the middle of the thigh was advised, but was refused. Roentgenotherapy was then advised and begun March 5, 1906. The patient was treated six times a week for six weeks; then three times a week for three weeks. In all she was given forty-seven treatments in three months. She has not been treated since then and is still perfectly well, seven years afterward.

A series of roentgenograms were made Feb. 20, April 7 and May 3, 1906, and Aug. 8, 1907, April 27, 1908, and April 5, 1912. These studies show a progressive increase in the quantity of lime salts, beginning first by a deposit beneath the periosteum covering the tumor, or at least at its periphery, and gradually extending into the center, so that at the time of stopping treatment the bony periphery was about ⅛ inch thick. At the end of fourteen months the tumor had approximately the density of the normal bone, but showed a number of elongated small cavities, which probably replaced the medullary cavity. It was then reduced to about two-thirds of its original size. Since that time there has been no appreciable change.

This case shows the following interesting points: 1. The clinical, roentgenologic and microscopic diagnosis was of sarcoma. 2. It was clearly an osteosarcoma of the medullary type. 3. The healing under the influence of the Roentgen rays began at the periphery and was indicated by a gradually increased deposit of lime salts, until it had reached the density of normal bone. 5. The tumor was only reduced to two-thirds of its original size. 6. The patient has remained well over seven years, during which time she has been married and has followed the ordinary affairs of life.

CASE 2.—Miss M. S., aged 23, was referred to me by Dr. Albert Cole of Indianapolis, March 29, 1909. Her right leg had been lame, stiff and painful since May, 1908. At the time of my examination by means of the Roentgen rays, she had a medullary or central sarcoma involving the upper 2½ inches of the fibula. The tumor was about four times the diameter of the fibula and showed no evidence of lime salts, except the faintest trace on one side. To all appearances the tumor seemed to be a duplicate of that in Case 1 except that it was more advanced. The patient refused operation absolutely.

She was treated with the Roentgen rays at intervals during a year, receiving about ninety exposures. There was

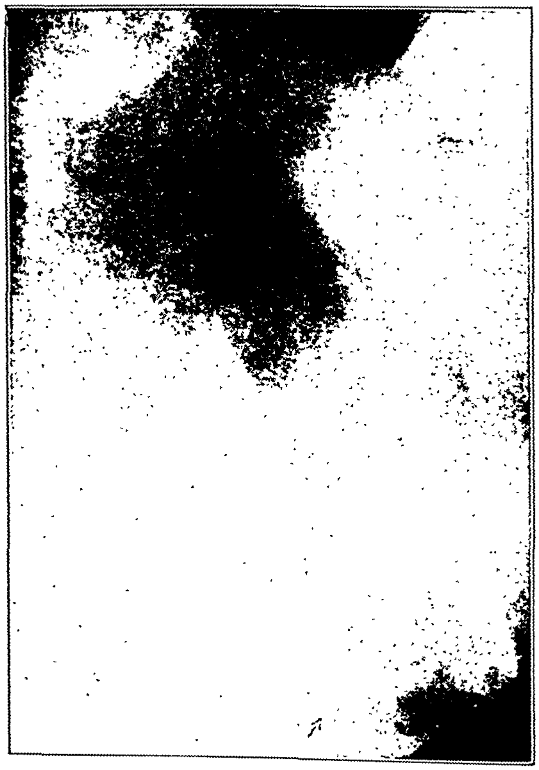

Fig. 6, Case 3.—Nearly complete calcification of the tumor (June 14, 1912).

slight increase in the lime deposit, but at no time definite evidence of reorganization. In May, 1910, the patient returned with definite evidence of fluctuation. She consented to have this incised and drained under promise that the leg would not be amputated. Incision showed an abundance of creamy pus, and Dr. Laplace, who operated, believed that it was tuberculous. The wound was curetted. Some of the scrapings were sent to Dr. Henry S. Wieder for microscopic study. He found the growth to be a spindle-cell and giant-cell sarcoma. Following the operation the patient developed some fever, and there was a continuous discharge of pus from the wound.

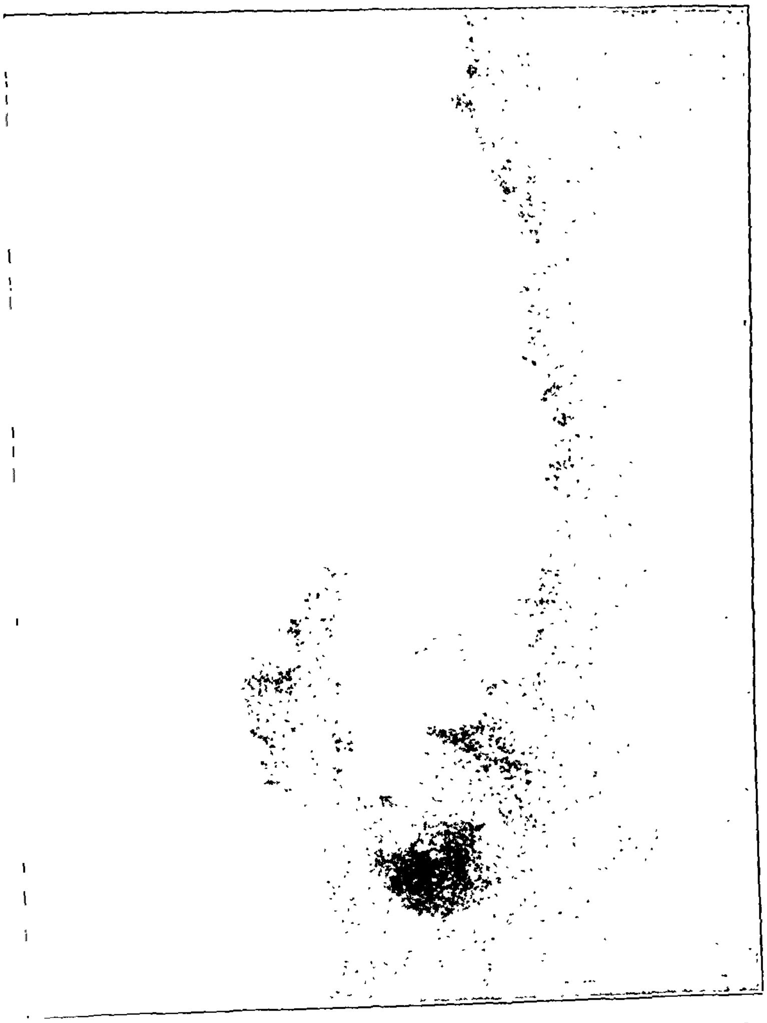

Fig. 7, Case 4.—Osteosarcoma of ilium. Notice fracture of the tumor (Jan. 6, 1909).

Repeated roentgenoscopies after the curettement showed a progressive deposit of lime salts, but little tendency for the wound to heal. The general appearance now was that of an osteomyelitis. Eight months after the curettement, Dr. R. F. Morris of Houston, Tex., wrote that the ulcer looked malignant, and had the appearance of an epithelioma. The patient then consented to an amputation of the leg and has remained quite well the two years since. The pathologic diagnosis by Dr. E. F. Cook was "myeloid sarcoma."

The points of interest in this case are: 1. The location and type of the osteosarcoma were almost duplicates of those in Case 1. 2. It was farther advanced, and probably did not have enough of the periosteum left to effect the deposit of lime salts. 3. The tumor degenerated into what seemed to be pus (a condition observed in another case of sarcoma of the soft tissues of the neck, which proved to be sarcoma). 4. The treatment probably helped to limit the disease since there has never been any evidence of metastasis in five years.

Case 3 (Figs. 5 and 6).—Mr. J. B., aged 39, was referred to me by Dr. John B. Deaver. Feb. 13, 1912, who stated, "I am morally sure that the growth is sarcoma and inoperable." The patient had at this time a growth infiltrating the anterior portion of the left thigh, about 6 inches long and 3 inches wide. He hobbled along with a cane, placing little or no weight on this leg.

Roentgenoscopy showed disease of the entire os innominatum below the middle of the acetabular cavity, or corresponding approximately with the ischium and pubes, and a bony tumor extending 6 inches down the thigh. The lime salts were almost completely absorbed in the diseased area, and the cancellous structure was entirely disorganized. The case looked like a hopeless one.

Roentgenotherapy was begun Feb. 15, 1912; and repeated daily at first, then three times a week, the patient receiving seventy-five exposures in all, during a year. He showed improvement at the end of three weeks, and in two months he was able to climb off and on a wagon and walked with only a slight limp. During the past fourteen months he has been driving a wagon regularly and now walks without the slightest limp, pain or inconvenience. To all appearances he is well. He has had repeated roentgenoscopies made at first at intervals of a month, and then less frequently. All showed a progressive increase in the deposit of lime salts, recognized at the end of the first month, and showed only slight increase after a year. The size and shape of the tumor showed practically no change. The surrounding tissues apparently accommodated themselves to the pressure of the tumor, so that it has given him practically no inconvenience. The skin showed no damage as a result of the roentgenotherapy.

This case is of interest because: 1. It involved the deepest bones of the body in a large muscular man. 2. It seemed hopeless from any other method of treatment. 3. Improvement was recognized both by the symptoms and by roentgenoscopies at the end of a month. The patient is apparently well sixteen months after beginning treatment.

Case 4 (Figs. 7 and 8).—H. G., a boy, aged 16, was referred to me for roentgenoscopy, Jan. 5, 1909, by Drs. Valentine Levi and H. C. Deaver. Five months previously while running a foot-race, he felt something snap in his right hip. He dropped to the ground, but in fifteen minutes got up and walked away. For a month after this accident any unusual movement gave him pain.

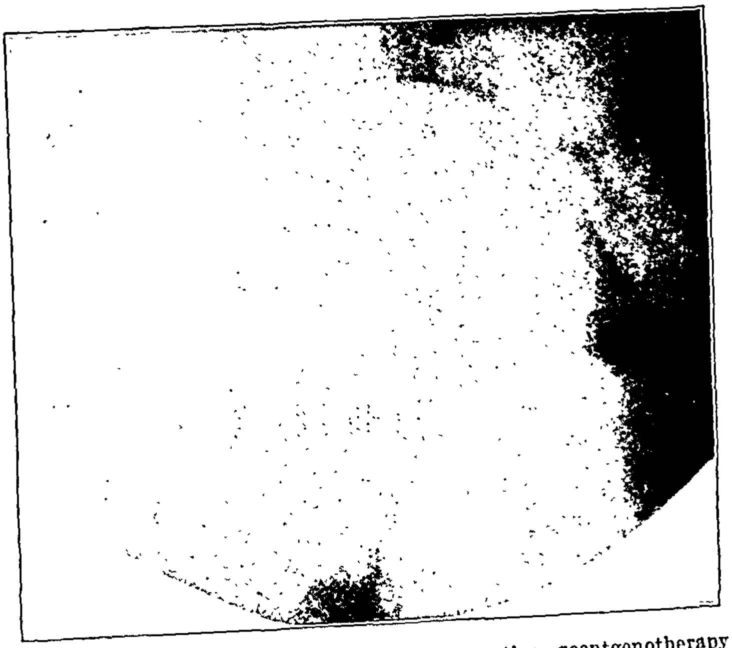

Fig. 8, Case 4.—After excision and active roentgenotherapy (July 8, 1909). (Plate reversed by the printer.)

Roentgenoscopies showed an osteosarcoma, about 2½ inches long and 1½ inches in diameter, growing from the ilium just above the acetabular cavity. This osteosarcoma was fractured during the foot-race five months previously (Fig. 7).

Dr. H. C. Deaver removed this osteosarcoma, Jan. 22, 1909, at the Stetson Hospital. Pathologic examination by Dr. Somers showed the tumor to be a giant-cell sarcoma at the center with spindle-cells at the periphery. During the first month after the operation Dr. Fisher gave twenty-one exposures of the Roentgen ray under my direction. During the next two months I gave sixteen treatments ending April 10, 1909. Since then, for over four years, the patient has remained perfectly well. He is at present traveling in Europe.

This case presents the following special points of interest: 1. The patient had no symptoms of the sarcoma which had developed until he fractured the tumor in a foot-race. 2. He suffered only occasional pain for five months afterward. 3. Excision followed by active roentgenotherapy has been followed by a cure lasting over four years.

CASE 5.—D. C., a girl, aged 14, was referred to me for examination by Dr. W. C. Batroff, Dec. 16, 1912. Nine months previously she injured the region of her left hip by a fall. Two days later a swelling appeared, which lasted two weeks. Two months after the injury the patient began to limp, and the hip became sore anteriorly.

Roentgenoscopy revealed no evidence of hip-joint disease or disease of the femur, but a large tumor shadow was found about the ilium, extending down over the hip-joint. The tumor contained no evidence of lime salts. I made a diagnosis of osteosarcoma.

Active roentgenotherapy was begun and continued over a period of three months; forty-four treatments were given, which were carried to the limit of skin tolerance. There was no evidence of deposit of lime salts; the tumor continued to grow until now its diameter is more than half the diameter of the body, and the patient is in the terminal stage of the disease. I believe now that the tumor is a chondrosarcoma, springing from the cartilage between the body and the epiphysis of the crest of the ilium, and because it is this type of tumor I have failed.

CASE 8.—E. B., a boy, aged 15, was referred for treatment by Dr. William L. Rodman, Oct. 29, 1902. He had been operated on by Dr. Rodman for osteosarcoma of the left side of the upper jaw two years previously. A recurrence, which now involved the entire anterior surface of the upper maxilla, had been noticed five months before he came for roentgenotherapy. He received sixty treatments in eight months. There was some reduction in the size of the tumor, and he has remained well now eleven years. The lower part of the left superior maxilla is still enlarged and very hard, but is quite well. The overlying skin shows some telangiectases.

CASE 9.—S. W., a boy, aged 9, was referred to me for roentgenotherapy, April 4, 1909, by Dr. Stillewell Burns. He had an osteosarcoma about the size of a peach stone in the right upper jaw, in the cuspid region. He had been suffering from pain for about two months. Roentgenoscopy revealed irregular destruction of the cancellous tissue, such as is seen in sarcoma. The patient was examined, and a section removed by Dr. M. I. Shamberg, April 24, 1909. He had been treated by the rays eight times preceding this section, and there was some reduction in the size of the tumor. Microscopic examination by Dr. H. S. Wieder showed it to be a spindle-cell sarcoma. He received 120 treatments (each treatment being two-tenths of a full erythema dose) in six months, when he seemed to be well. He has remained well for over four years. The cuspid tooth is twisted on its axis so that the cutting edge is at right angle to the normal, and there remains some thickening of the bone at this point, but otherwise nothing abnormal.

This case shows the following instructive points: 1. What at first seemed to be a benign epulis proved to be an osteosarcoma of spindle-cell type. 2. Surgical treatment, even if successful in removing the disease, would have demanded considerable resection of the jaw, with at least considerable deformity. 3. The healing process led to a twisting of the tooth but did not interfere with its growth and development. 4. The patient has remained well over four years.

CASE 12.—W. H., aged 7, was referred for treatment by Dr. D. B. Kreider, Aug. 22, 1911. During six weeks a tumor had developed in the left lower jaw in the region of the cuspid and bicuspid teeth. It was now about 1½ inches long, 1 inch wide, and elevated about ½ inch above the surrounding surface. A section examined by Dr. H. S. Wieder showed the tumor to be a giant-cell sarcoma. Roentgenoscopy showed a disturbance in the cancellous structure of the alveolar process and irregular absorption of lime salts. The patient was treated by the Roentgen rays fifty-two times in four months, each exposure *giving about two-tenths of an erythema* dose. At the end of this time he was apparently well. He has remained well eighteen months since, and I believe that he is permanently cured. He has no loss of tissue, no deformity, and simply has some displacement of two teeth which have erupted since the tumor has healed, and were either displaced by the growing tumor or by the sclerosis following the treatment. The cancellous tissue is slightly more dense than normal.

This case, like Case 9, shows: 1. Healing without interruption of the development of the teeth, but followed by some displacement. 2. Healing without damage to overlying or underlying tissue.

TECHNIC

A review of the brief reports of the foregoing cases will show that this treatment and these observations have extended over a period of eleven years; the technic has, therefore, undergone a progressive evolution, the duration of the treatment and the number of exposures being very much reduced in the later cases. For the sake of brevity I shall refer only to the principles governing the modern technic. These are:

1. The rays must have good penetration, or they will be absorbed by the overlying tissues before reaching the bony tumor. Even with the most penetrating rays the greater proportion will be absorbed by the superficial tissues. The most careful attention is therefore necessary to keep the tube in good condition during the entire treatment. The rays should have a penetration of from 7 to 8 of the Benoist scale.

2. The quantity of rays should be measured carefully during each application, and the limit of the erythema dose should be reached as quickly as possible, but should not be exceeded. The duration of each application and the frequency will depend on the individual operator's technic and apparatus, but when an erythema dose has been given at any one area of skin, this one area should receive no more treatment for at least two weeks. To measure the dose I use the Sabouraud pastille and the Holzknecht modified scale, or radiometer.

3. The skin should be protected by filters. For this I now use a piece of sole-leather ⅛ inch thick, and from 1 mm. to 3 mm. of aluminum. This, of course, decreases the total quantity of rays, but gives a greater proportion of penetrating rays in comparison with those absorbed in the superficial tissues. It must not be forgotten that a patient can be burned through filters, and a burn is always a disadvantage.

4. Cross-fire application of the rays consists in directing them toward the center of the tumor from as many angles and through as many different areas of skin as possible. In this way the proportional deep dose is greatly increased, and it is possible to make the dose in the tumor equal to that absorbed by the skin. With such technic massive doses can be given safely.

CONCLUSIONS

1. Osteosarcomas heal by a progressive deposit of lime salts in the tumor areas, until the tumor area attains the solidity and density of normal bone.

2. This process usually begins within a month and is progressive for a year or more, continuing long after the roentgenotherapy has been discontinued.

3. In the twelve cases treated, including the inoperable and recurrent, seven, or over 58 per cent. of the patients have completely recovered and have remained well from five months to eleven years. One other patient had nearly recovered, interrupted treatment, and remained free from symptoms five months, when a recurrence followed traumatism. In only one case was there no improvement.

4. Skilful treatment should be given in any inoperable case and should follow when operation seems advisable.

5. When operation will result in deformity or serious loss of bone, roentgenotherapy should be tried for at least a month.

6. The treatment should be given by some one who is familiar with the technic of deep roentgenotherapy.

1321 Spruce Street.

WHAT CAN BE DONE IN CANCER WITH ROENTGEN RAYS?*

WILLIAM ALLEN PUSEY, A.M., M.D.
Professor of Dermatology in the University of Illinois
CHICAGO

Undoubtedly the Roentgen ray as a therapeutic agent in cancer has lost ground in the estimation of the profession. It has gone through the familiar cycle: promise, exaggerated expectations and statements, disappointments and reaction. In the case of Roentgen rays the course has been particularly unfortunate; the agent lends itself so readily to sensational exploitation and its application is so outside the usual routine of medical and surgical procedure that many conservative men have neither undertaken to use it, nor—what is more unfortunate—made themselves familiar with what might be properly expected from it or with its actual results; while on the other side its haphazard application is so easy that many untrained men have used it with much damage to its reputation.

What are the facts? Is the skepticism concerning it a just and temperate judgment? Has it failed to live up to its early reasonable promise, or is it simply suffering from lack of appreciation and from ignorance in the minds of the profession of its actual accomplishments? To confine ourselves to the question in hand, has it proved an addition of any practical value in cancer—using that term to include all forms of malignant growth? Can anything practical be done with it that cannot be done by better established methods, or is it of so little use that it may be properly neglected in the treatment of our cases of cancer?

The most cursory observation leaves no doubt that Roentgen rays can destroy carcinoma tissue on the surface of the body. This is done most readily, perhaps, in basal-cell carcinomas—rodent ulcers—but it can be done also in typical squamous-cell epitheliomas. The statement is sometimes made that in true squamous-cell carcinoma, Roentgen rays will not destroy the lesions. In refutation of this, I have offered the accompanying case (Figs. 1 and 2), the first case of squamous-cell carcinoma (Fig. 3) that I treated with Roentgen rays. The patient remains well to-day, twelve years after healing, with the cosmetic result shown in Figure 3. I could offer scores of similar cases of squamous-cell carcinoma and as many of rodent ulcers. The accompanying illustrations of a few cases are selected as offering certain visible evidence of Roentgen-ray effects in cutaneous carcinoma (Figs. 4 to 7).

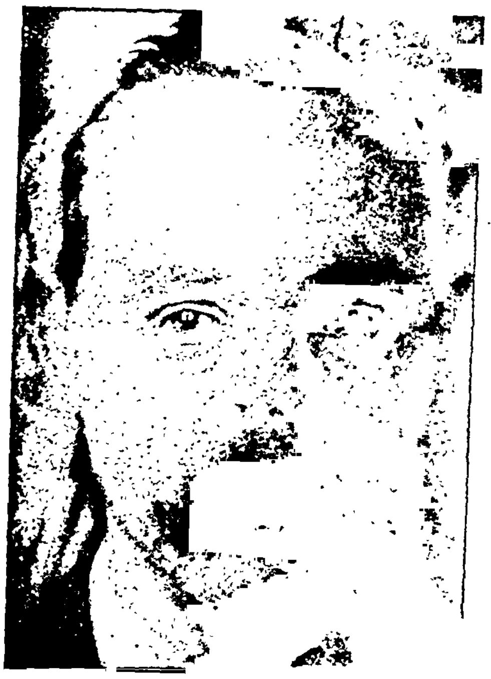

Fig. 1.—Squamous-cell epithelioma of the nose, May, 1901.

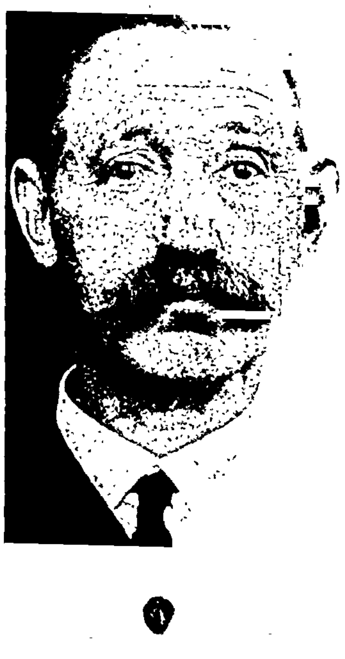

Fig. 3.—Result of Roentgen-ray treatment of lesion shown in Figure 1, March, 1912.

In my experience the type of epithelioma makes little difference; basal cell or squamous cell, any epithelioma on the surface may be destroyed with Roentgen rays. Some lesions yield much more readily than others; but this variability does not amount to complete resistance in any case, and the point I wish to make here is that epithelioma tissue in the skin can be destroyed by Roentgen rays with practical certainty.

If the applications are properly graduated, the carcinoma cells degenerate, disappear and are replaced by healthy scar tissue. Various men, including myself, have described the microscopic changes that occur in this process, so that I shall not delay to do it again here, but shall only call attention to the fact observed in sections taken during various stages in the process, that at the beginning we have carcinoma and at the end we have in place of it firm healthy scar tissue.

As to Roentgen rays in epithelioma I believe it may be said almost without reservation that any epithelioma which has not metastases and which has not deeply involved the subcutaneous tissue may be symptomatically cured by Roentgent rays. By symptomatically cured, I mean converted into healthy scar tissue, as healthy scar tissue as can be obtained after the excision of epithelioma. The superficial extent of the carcinoma is, of course, a factor of some consideration in the prognosis; but the most extensive epithelioma that I have seen I have symptomatically cured with Roentgen rays. I have seen lesions involving areas of from 30 to 40 or 50 square inches converted into healthy scar tissue.

---

* Owing to lack of space this article is here abbreviated by omission of four photomicrographic studies of diseased tissues. These are presented in the Transactions of the Section and in the author's reprints.

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

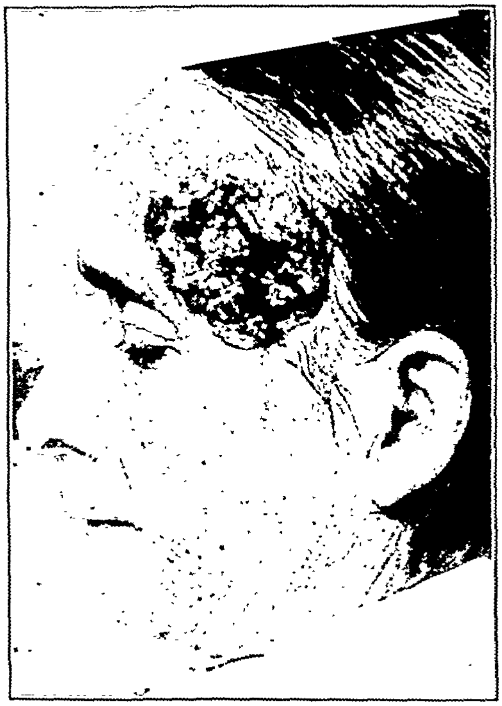

Fig. 4.—Epithelioma of face.

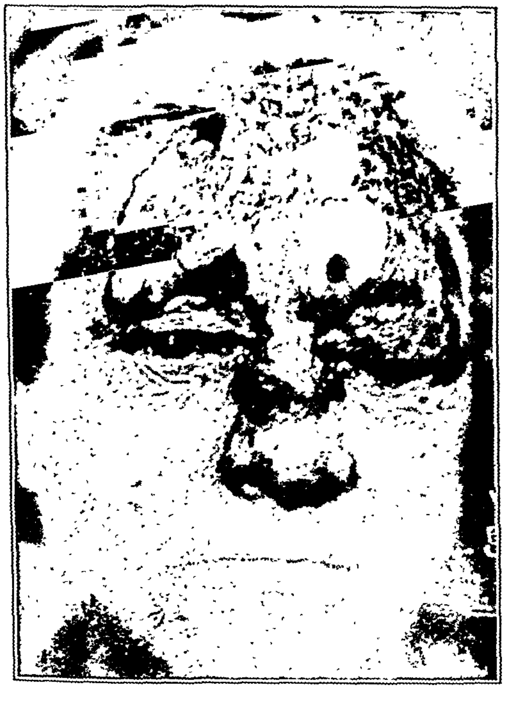

Fig. 6.—Epithelioma of temple.

When there is deep involvement of subcutaneous tissues, as in epitheliomas invading the orbit or extending down deep into the bones of the face, Roentgen rays may fail; but I have seen unexpectedly successful results in cases of this sort, as, for example, in epitheliomas involving the bones of the nose. When there are metastases in the contiguous lymph-nodes, Roentgen rays usually fail, but here likewise at times we have successful results.

As to the permanence of the results in epithelioma, some of my cases have gone more than ten years without recurrence, and I believe that whenever you are able to get a satisfactory scar you may count on a permanent result. As regards permanency of results, I believe the cases will bear a fair comparison with those treated by any other method. As to the range of application of Roentgen rays in epithelioma, it may, in my opinion, be said that any case of epithelioma is suitable for treatment with Roentgen rays in which, if a wise surgeon were

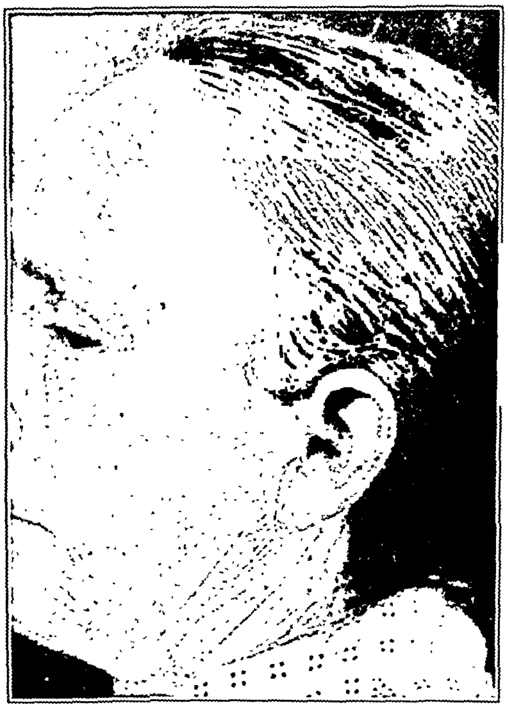

Fig. 5.—Result of Roentgen-ray treatment of patient shown in Figure 4.

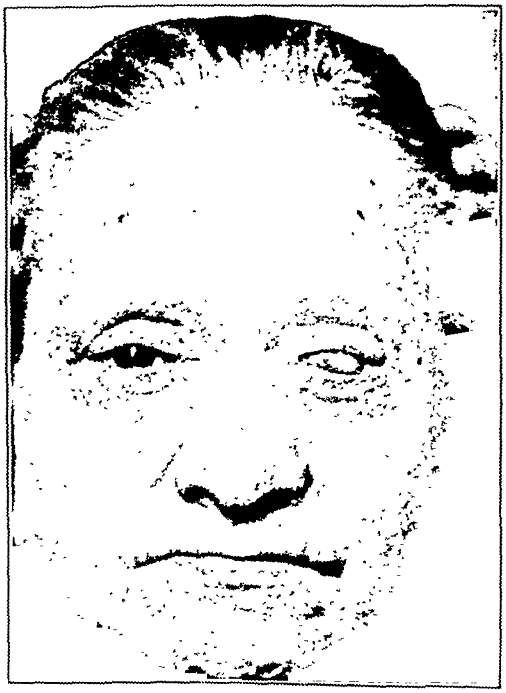

Fig. 7.—Result of Roentgen-ray treatment of patient shown in Figure 6.

operating, he would not feel called on to remove the contiguous lymph-nodes. If the case is one in which the removal of the contiguous lymph-nodes is indicated, it should be treated surgically, and not with Roentgen rays. That statement, I trust, covers the question of the treatment of epitheliomas of the lip with Roentgen rays.

The foregoing paragraph is a practical repetition of a statement I made seven years ago, and my longer experience makes me more than ready to stand by this position now.

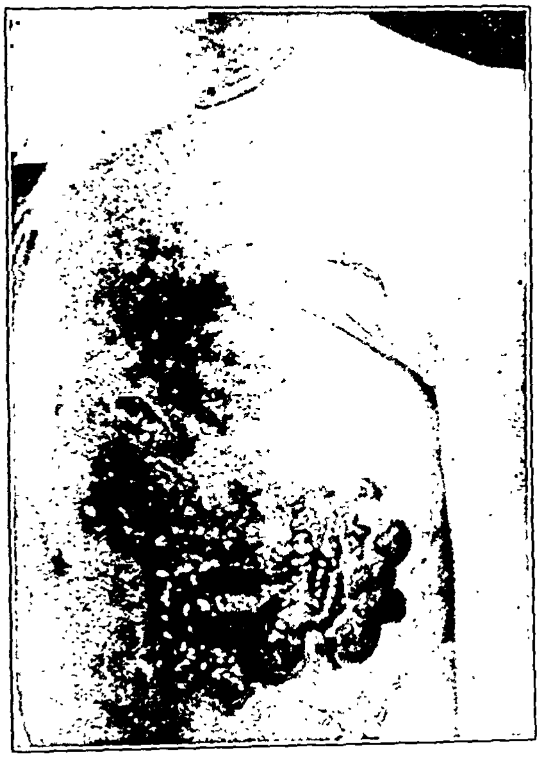

Fig. 11.—Recurrent carcinoma of breast.

But granting that epitheliomas on the surface can be destroyed by Roentgen rays, what evidence have we that deeper malignant growths can be affected? From my experience I can produce much evidence on this point, as can many other men who have used Roentgen rays in this field. Take the following cases for examples:

REPORT AND DISCUSSION OF CASES

Case 1.—Figures 11 and 12 show the effects in one of my earliest and most striking cases of recurrent carcinoma of the breast treated with Roentgen rays. In this case a great mass of carcinoma, recurrent after repeated operations by Dr. Christian Fenger, had entirely disappeared and been replaced by smooth, healthy looking scar tissue after four months of Roentgen-ray treatment.

Case 2.—Miss ——, aged 49, had the left breast removed by Dr. Nicholas Senn in February, 1900; this was followed by a recurrence which Dr. Senn removed in October, 1900. She had a second recurrence which Dr. A. J. Ochsner considered inoperable; he sent her to me for Roentgen-ray treatment in November, 1901. She had a dense deep-seated mass of carcinoma tissue involving the chest wall, with coin-size ulcer at two points. This all disappeared under Roentgen-ray treatment. Six months later she developed a hard mass under the nipple of the other breast. This also disappeared under Roentgen rays. This patient went on until 1907—nearly six years—without recurrence and in comfort, during all of this time occupying a laborious position of responsibility. In discussing this case in April, 1902, Dr. Ochsner expressed the opinion that she would surely have been dead at that time, but for the effects of Roentgen rays.

Case 3.—Mrs. ——, aged 45, referred to me by Dr. T. A. Davis, had the left breast removed for carcinoma in May, 1901. In spite of moderate prophylactic Roentgen-ray exposures, nodules appeared in the axilla, with swollen arm, early in 1902, and soon afterward there developed hard lymph-nodes in the supraclavicular space. Under very vigorous Roentgen-ray exposures, carried to the point of producing ultimately atrophy and telangiectasia of the skin of the areas exposed, all of the carcinoma masses disappeared, with the exception of small palpable masses representing the lymph-nodes. Although the condition had hitherto been regarded as inoperable, it was decided now to remove these lymph-nodes. On operation, instead of a mass of lymph-nodes infiltrating the jugular wall as had been feared, small masses of fibrous tissue were found which were easily dissected out without damage to the vessels. The patient was well nine years later and I believe remains so now. The inevitable natural career of such a patient is, of course, death in a period measured by months.

The following two cases of primary carcinoma of the breast are interesting in this connection:

Case 4.—Mrs. C. C., aged 45, was referred to me by Dr. C. Z. Aud of Cecilian, Ky., in January, 1902, with a diagnosis of carcinoma of the breast for which operation had been urged repeatedly but refused. There was a large nodular hard movable mass in the right breast, with retraction of the nipple. It had been slowly enlarging for four years accompanied during the last year by frequent shooting pains. The patient was exposed to Roentgen rays regularly from January to May, 1901, and had one series of exposures in June, 1903. The result was complete disappearance of the tumor and she is living and well to-day with a breast free from tumor—eleven years after coming under treatment.

Case 5.—A similar case was that of Mrs. C., aged 55, referred to me in October, 1902, by her son, a physician, and Dr. William E. Quine of Chicago with a diagnosis of carcinoma of the breast. In the right breast there was a lemon-sized nodular mass just beneath the nipple, which had been noticed two weeks before. One lymph-node was palpable in the axilla. Operation was refused. The patient had nearly a hundred Roentgen-ray exposures during a period of three years. I saw her living and well in February, 1910, eight years after. The breast tissue was perfectly soft, and there was no suspicious point, in either the breast or the axilla. I believe she remains well now.

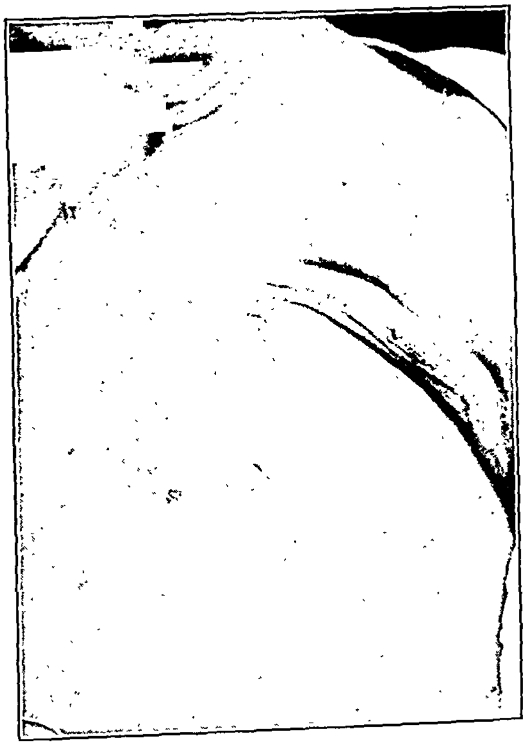

Fig. 12.—Result of Roentgen-ray treatment of case shown in Figure 11.

The clinical diagnosis of carcinoma was as clear as possible in both of these cases and they had been regarded as carcinoma by numerous competent consultants. These cases constitute two of the three cases of operable primary carcinoma of the breast which I have treated; the third was a failure. They are not recited as an argument in favor of using Roentgen rays instead of operation in operable cancer of the breast, but as evidence of deep-seated Roentgen-ray effect on cancer.

Similar evidence is furnished by the post-mortem findings in the following two cases:

CASE 6.—The first patient, an old woman referred to me by Dr. E. Wyllys Andrews of Chicago, had a large primary carcinoma of the breast without involvement of the skin, with enlarged axillary lymph-nodes, and with spinal metastasis when the treatment was begun. The patient had vigorous Roentgen-ray exposures lasting about a month, with the production of a dermatitis which subsided completely before her death, about three months after the treatment began. Post mortem it was found that the breast was a mass of connective tissue without any carcinoma tissue remaining. The same was true of the axillary contents; they were converted into a mass of connective tissue.

CASE 7.—In the second case, that of an old woman referred to me by Dr. J. B. Murphy, there was a large primary carcinoma of the breast without involvement of the skin and with enlargement of the axillary lymph-nodes. The patient had vigorous treatment for six weeks, with the production of only a mild reaction. Two months after the treatment, Dr. Murphy wrote me, "I saw Mrs. ——— on last Friday. The carcinoma of the breast has entirely disappeared, but she is suffering from a gastric disturbance from which I fear she will die." She died soon afterward and post mortem it was found by Dr. W. A. Evans that the tumor had been converted into a small fibrous mass. Microscopically it consisted of fibrous tissue bands with a few islets of epithelium, some of the epithelium being in a fair state of preservation, but most of it in a state of advanced retrogression. In these two cases we had carcinoma tissue beneath skin and fat destroyed without destruction of the normal surrounding tissue.

I could recite many more cases of cancer of the breast in evidence of the destructive effect of Roentgen rays on carcinoma tissues situated relatively deeply, but my object now is not so much the presentation of cases as the production of a few definite facts.

A considerable number of cases of sarcoma presenting similar evidence of a selective destruction of sarcoma tissue could be produced, but because the results are so similar I shall give the briefest statement. In general, sarcoma tumors diminish under Roentgen rays more readily than do carcinomas, but because of the more rapid disssemination of sarcomas, radical benefit is less frequent. I have, however, some cases of sarcoma in which most unexpected good results have occurred—results that have lasted a dozen years or more.

CASE 8.—One good result is a case of mixed round and spindle-cell sarcoma in Scarpa's triangle in a woman operated on by Dr. William J. Mayo in April, 1905, and referred to me by him a few weeks later with a very unfavorable prognosis. There was a reappearance of the tumor, which disappeared under Roentgen rays. She was well in August, 1911 —six years later—and I believe is well now.

CASE 9.—Another is a man operated on by Dr. Alexander Hugh Ferguson in 1907 for osteosarcoma behind the clavicle, and referred to me February, 1908, with a mass behind the site of the clavicle, which had been removed, and in the supraclavicular space. This man remains well with no evidence of sarcoma at present—five years after he was regarded as hopeless. He is a vigorous man, active in an exacting occupation.

These cases are of course selected ones; I have seen many cases that have failed, as fail many cases must with a disease like cancer; but these selected cases are only a few of a great many such cases that I might select to show equally striking results. So many cases like these can be produced that they cannot be explained away on the theory of the occasional spontaneous subsidence or disappearance of cancer.

I cannot here present any extensive data on the prophylactic value of Roentgen rays after operation; but I would like to recount briefly one case of cancer of the breast:

CASE 10.—Mrs. ———, aged 45, a physician, came to me in May, 1902, in fear of a recurrence in the chest wall after carcinoma of the breast. Her family history was as follows:

Paternal History: Grandfather, carcinoma of stomach; grandaunt, carcinoma of breast; granduncle, carcinoma of stomach; uncle, carcinoma of intestine; uncle, carcinoma of intestine; brother, carcinoma of intestine; cousin, supposed carcinoma of intestine; cousin, carcinoma of intestine.

Maternal History: Aunt, carcinoma of uterus; aunt, carcinoma of breast, removed, no recurrence; cousin, carcinoma of breast, removed, subsequent history not known. In all ten or eleven carcinoma cases of which she knows in her family in three generations.

The patient's own history was as follows: Left breast amputated for carcinoma, December, 1899; muscles removed from left side, January, 1900; right breast removed, April, 1900; nodule removed below left clavicle, August, 1901; nodule removed above clavicle, February, 1902; nodule removed in neck, March, 1902; nodule removed in neck, April, 1902. Two of the operations were done by Dr. W. W. Keen of Philadelphia, and some others by his associates.

The patient came to me in May, 1902, for Roentgen-ray exposures. She had seven series of exposures between May, 1902, and November, 1905, in all 127 treatments. She has gone now eleven years without further recurrence. It may be pointed out that she had swelling of the supraclavicular lymph-nodes eleven years ago, and such cases are practically invariably fatal. Of course, she might not have had any further recurrence without Roentgen rays, but I venture to believe it would be hard to convince her, with her experience, of that fact.

What is the practical bearing of such facts? And in view of them, what use should be made of Roentgen rays in cancer? In the first place, I would point out that the selective destruction of cancer tissue by Roentgen rays (and radium) is a unique thing. It is something that has never been done before and that no one can now do in any other way. And such cases as I have referred to above show that some practical effect can be produced in cancer after all has been done that is possible by mechanical or other methods of gross destruction. Many cases cannot be helped, but some can be saved. And until a specific remedy for cancer is found, of which there seems little promise now, patients are entitled to the unquestionable prospects of benefit that Roentgen rays offer in many cases. From such a point of view I have used Roentgen rays in cancer for many years and I am sure that the agent has saved a good many patients from an impending death; it has added in the aggregate many years of life in comfort to patients whom it has not cured, and it has saved much suffering to many others whose lives it has not prolonged. On the other side it has often failed; but I believe it has not added to the misery or made worse the lot of any patient. An agent of which these things can be said in so wretched and intractable a disease as cancer is entitled to respect, and is worthy of a better opinion than the skepticism with which it is now considered by many minds.

For example, surgeons as a rule, I believe, fail to appreciate the value of Roentgen rays as an adjuvant to surgery in the treatment of cancer cases. Roentgen rays are useless in many cases of cancer; therefore the method is condemned as useless in all cases, and operation or nothing insisted on always, just as though operation were not useless or worse than useless in many cases also. The Cancer Campaign Committee of Surgeons of North America in its public statement on cancer says, "Cancers can be successfully treated by the knife. . . . there is no chance of recovery except in surgery." This last sentence is not true. The first sentence also is true for the most part only of cancers situated superficially in the body, and many cases of that sort have been cured for a hundred years by other destructive measures than surgery. Surgery is the method of preference for most cancers, and it is well for surgical organizations to teach the public that fact. But if there is anything that surgery should be humble about and alert for help in, it is cancer.

SUMMARY

The effects of Roentgen rays on cancer tissues and clinical experience indicate the use of the agent in cutaneous epitheliomas, and in localized inoperable cancers near the body surface; and further, I believe that the same facts constitute a logical demand that Roentgen rays be used as a measure of prophylaxis after operations on localized cancers near the surface of the body. I specify localized cancers near the surface, because experience has shown that in cases in which the disease has become widely disseminated, and in cancers in the deep cavities of the body, Roentgen rays are practically without avail.

ROENTGENOTHERAPY IN MEASURED MASSIVE DOSES *

SIDNEY LANGE, M.D.
CINCINNATI

When I accepted the invitation to take part in the program of this section I planned to report some results of roentgenotherapy in massive doses in certain types of malignant conditions which had heretofore not only been refractory to roentgenotherapy, but also, because of their location and anatomic relation, had been regarded as unfavorable from the surgical point of view. I am unfortunately not able to make this report for two reasons: first, because the most of the cases under observation have not been under treatment long enough to warrant drawing conclusions, and secondly, because I am not sure that I have overcome certain obstacles in the technic of the administration of efficient irradiation of these cases. I shall therefore limit myself to some remarks on the measured massive dose.

By efficient irradiation is meant the administration of a dose which will accomplish the desired result; of course, the desired result must be a possible and practical one. In other words, the pathology of the condition selected for roentgenotherapy must be well considered. We must know by experimental deductions or clinical experience that the Roentgen ray will influence the lesion in the desired way. For instance, it is a commonly accepted fact that the Roentgen ray will cause degeneration and destruction of certain cells which we call cancer cells. Any one can demonstrate this by experimentation. But most important is the fact that the Roentgen rays will destroy cancer cells without injuring normal tissue cells which have been subjected to the same dose of Roentgen rays. Because the Roentgen ray does this, it is said to have a "selective" action on cancer cells. What is really meant by the term "selective action" is that the cancer cells are more susceptible to the Roentgen ray, either because they have a higher coefficient of absorption for Roentgen rays than normal tissue cells, or because owing to their subatomic make-up or abnormal metabolic activity, they are less resistant to the influence of the Roentgen ray.

Early in the Roentgen era Guido Holzknecht made the simple yet classic statement that every living cell which has absorbed Roentgen rays will suffer a chemical change which may produce no appreciable effect, or may result in stimulation, irritation or degeneration. The effect of Roentgen-ray exposure on any cell will depend on two factors: (1) the amount of rays absorbed by the cell as determined by certain conditions which are imperfectly understood, chief of which is perhaps the ultrachemical structure of the cell, or in gross terms, the morphology of the cell, and (2) the susceptibility of the cell to the Roentgen ray, the so-called radiosensitiveness of the cell. Among the factors determining the sensitiveness of the cell to the Roentgen ray are the function of the cell, its physiologic relation to the rest of the organism, and its metabolic activity.

The problem for the roentgenotherapeutist then, resolves itself into the fulfilling of three requirements:

1. Certain cells or tissues must be supplied with the kind of rays or quality of rays which they can absorb, for cells are influenced only by absorbed rays.
2. The rays supplied to these cells or tissues must not injure the surrounding overlying or underlying normal tissues.
3. The rays must be supplied in sufficient number or quantity to bring about the desired changes.

In the present state of our knowledge of roentgenotherapy we are not certain that any of these conditions can be fulfilled absolutely. Yet we are fairly well acquainted with the differences in the biologic action of hard and soft rays, and our technic has advanced to the point of enabling us to produce at will rays which are for the most part hard and penetrating, or for the most part soft and non-penetrating.

In the fulfilment of the second requirement, we are aided largely by the fact that as a rule tissues which are normal morphologically and physiologically are much more resistant to the influence of the Roentgen ray than are tissues which are abnormal or pathologic, from either the morphologic or the physiologic aspect.

The third requirement, namely, that of supplying the sufficient, yet not excessive quantity, is the one that concerns us chiefly at this moment. The introduction of the measured dose promises to fulfill this requirement and is one of the most important forward steps in the history of roentgenotherapy. Roentgen-ray dosage is thus relieved in a measure at least from the stigma of inaccuracy and empiricism, and is placed on a rational biologic basis. Analogous to drug therapy in order to elicit the fullest physiologic effect, the full physiologic dose must be administered. To give small doses of Roentgen rays when the maximum effect is desired is analogous to giving 5 grains of potassium iodid at a dose when it is desired to elicit the full therapeutic action of the drug. The full therapeutic action of the Roentgen ray is elicited in the tissue only when by the complete saturation of the tissues the fullest reaction is excited which is compatible with the integrity of the overlying or surrounding normal tissues. Roentgen-ray dosage which falls short of this amount can elicit the full effect only when by frequent repetition of the dose

---

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

the so-called cumulative action in the tissues becomes manifest. To await the development of accumulative effects following repeated small doses is not only uncertain, since the saturation point may never be reached, but it also invites chronic changes in surrounding normal tissues. It is furthermore wasteful of time and energy. In giving Roentgen-ray treatments we are delivering physical energy to the tissues, and the required amount must be delivered in sufficient mass to excite a reaction and thus overcome the inertia of the tissues. We may cite a homely mechanical analogy in the energy required to drive a spike into a board. Repeated small blows from a tack-hammer will never accomplish the results of a single blow with a sledgehammer, although the total amount of energy delivered may be the same in each instance.

I need not refer to the early days of the Roentgen era when by the fractional dose method, small and often inefficient doses were given which extended the treatment over many months. While in many cases and at the hands of certain men brilliant results were obtained, yet not infrequently the results were incomplete or failures. The small doses often stimulate the lesions instead of checking them; again, the lesions acquired a resistance or tolerance for the Roentgen ray which negatived the results. Furthermore, the long-continued exposures invited late secondary changes such as atrophy, etc., in the surrounding tissues with the possibility of later and more dangerous sequelae.

A comparison of past results obtained by the fractional dose method with more recent results obtained by the single massive dose method has renewed enthusiasm in roentgenotherapy. By way of comparison I recall treating a large basal-celled cancer on the cheek of an old woman for a period of six months before effecting a cure, and more recently of treating a lesion almost identical in location and character by the single massive dose method and effecting a cure in five weeks without repeating the treatment. Another instance, fresh in mind, is that of a doctor who was referred for treatment with an epithelioma of the lower lip of eighteen months' standing, involving more than half of the mucocutaneous margin, and more than ¼ inch deep. Submental lymph-nodes were not palpably involved. In the opinion of several surgeons it was an operative case, but a brief trial with the Roentgen ray was suggested. One massive dose was given and at the end of four weeks most of the infiltration was gone and the epithelium had completely covered the area. The patient remains free from recurrence to date, but presents himself for observation once a month, at which times light prophylactic doses have been given.

I need not multiply the evidence to support the efficacy of the single massive dose. Interesting to note in this connection is the fact that not infrequently the epithelium will completely close over an ulcerated skin cancer following a single massive dose before all of the underlying infiltration has disappeared, but without further treatment the remaining infiltration will entirely disappear. In some instances it has been necessary to repeat the dose, either because there was underdosing through faulty technic at the first treatment, or underdosing at one angle or margin of the lesion. The prickle-cell type is of course more resistant than the basal-cell type, and may require repetitions of the treatment. In the fungous types of skin-cancer in which the lesion is of considerable thickness, several doses may be required, which is in harmony with our knowledge of the physical principles of roentgenotherapy. The physical dose (or crude dose) is the amount of rays absorbed by any tissue divided by the number of layers of cells or thickness of the tissue. Hence, in treating a thick or fungous lesion the lower layers of cells will be underdosed, owing to the loss of intensity due to absorption. It is possible that a preliminary curettement may facilitate the administration of the efficient dose to the lower layer of cells in one exposure and thus shorten the treatment.

The massive measured dose, while finding its most brilliant application in the treatment of skin-cancer, should by no means be confined to the treatment of superficial malignancy, but should be extended and applied to every field of roentgenotherapy. Chronic eczema, psoriasis and other chronic skin lesions are better treated by the measured massive dose than by fractional doses, although the dose administered need not always be the full erythema dose.

I have been applying this method to various forms of deep therapy with surprising results. An aluminum filter varying in thickness from 1 to 3 mm. is used, and the pastil is of course placed under the filter. This method has increased the efficiency of postoperative prophylactic treatment of malignancy and has hastened the improvement in recurrences.

Two neglected cases of cancer of the chin are under treatment. Both started from a cancer of the lip, and when the patients presented themselves for treatment, each had a large tumor involving lip, chin and neck, the tumor mass weighing perhaps half a pound and protruding several inches beyond the line of the chin. Under massive doses of Roentgen rays, both cases have improved remarkably. In one case practically all of the infiltration has disappeared and the parts have assumed normal proportions, except for a partial destruction of the lip.

In the roentgenotherapy of uterine myomas, climacteric hemorrhages, etc., the massive dose technic has been found superior to the fractional doses as shown by the statistics of Gauss in the Freiberg clinic. By means of the aluminum filter 3 mm. thick and a compression band to exsanguinate and thus desensitize the skin, it has been possible by Gauss, Schmidt and others to give as much as four times the erythema dose at one exposure and in one series extending over several days to subject the same area of the skin to from six to ten times the erythema dose without apparent injury. By varying the areas of skin exposed it is thus possible to deliver tremendous quantities of Roentgen rays to the deeper tissues. Gauss reports applications to the ovaries of more than one-hundred times the erythema dose in one series of treatments.

Cases of enlarged thymus in children have been cured in one or two massive treatments. This method seems to promise something in the treatment of certain forms of malignancy which are unfavorable for surgical intervention and which are likewise regarded as not amenable to roentgenotherapy. I refer to certain types of cancer about the gums, jaws and tongue. If treated surgically these cases demand heroic measures, producing great deformity and leaving a doubtful prognosis. In this class are especially included those cases of malignancy occurring at the angle of the jaws involving the gums and alveolar process of both upper and lower jaw, or malignancy of the tongue or jaws which extends beyond the midline, and which if treated surgically would mean a great *sacrifice of tissue*, with great deformity and a doubtful prognosis. As recorded results of massive roentgenotherapy in this class of cases is rather meager, I have undertaken to test out the method in a series of such cases which have been considered by surgeons to be unfavorable risks. The inaccessibility of many of the lesions has been the chief difficulty since the efficient massive dose must be delivered to each cancer cell. Special devices such as lead tubes to direct the rays to the proper areas, mouth gags and clamps to evert the lips, etc., are being used. In some cases a preliminary surgical operation such as splitting the cheek to expose the lesion seems necessary. One very favorable result has been achieved so far. The case was that of a cancer of the tongue involving the anterior part of the tongue and extending beyond the midline; a small submaxillary lymph-node was palpable. Under vigorous roentgenotherapy of the tongue and neck the infiltration of the tongue has disappeared and the lymph-node is no longer palpable. A symptomatic cure has been obtained and after a lapse of almost a year no recurrence is evident.

It would seem that the ability to administer the measured massive dose is a sine qua non of successful roentgenotherapy. As the technic is mastered the field of roentgenotherapy seems destined to broaden, which is shown by the successful treatment of certain gynecologic conditions by this method as practiced in many German clinics.

After the technic of measuring the dose in certain units has been mastered, the problem of how many units to give is still uncertain, and to a large extent dependent on individual judgment. In determining the amount required for the treatment of any condition, it must be remembered that the biologic or active dose is the physical (or crude) dose multiplied by the coefficient of susceptibility of the tissues under treatment.

In applying these heavy doses we must not be unmindful of the possible dangers, and possible late effects from the repetition of such doses. Iselin has recently shown that by the use of a filter the erythema dose may be frequently repeated without danger of late results, the danger limits varying in the different regions of the body. It is apparent, however, that such a method as this must remain in the hands of those specially trained and skilled in roentgenology.

5 Garfield Place.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. LANGE, PUSEY AND PFAHLER

Dr. L. T. LeWald, New York: I wish to confirm the statement of Dr. Pfahler in regard to the deposit of lime salt after treatment. The case I refer to was treated thoroughly with radium. It was under observation for about four months. It was an osteosarcoma of the head of the humerus of which a section was removed and pronounced sarcoma by Dr. Wood; Dr. Abbe made an incision and introduced radium. In about a month there was an increase in the lime salts. This increase has continued three months and the case is still under observation.

Dr. G. Betton Massey, Philadelphia: I wish to corroborate what Dr. Pusey said about the penetrating value of the Roentgen ray in some carcinomas by mentioning very briefly at least two cases of secondary growths in the neck above the clavicle—secondary to carcinoma of the breast—that have apparently disappeared under the roentgenotherapy. It is well known that absolutely no other method could have effected such results in these two cases. The terrible misuse of the Roentgen ray, aside from the mortality of some of the operators, shows a need of greater cooperation among members of the profession in order that the best may be done in a given case, whether it be some form of surgery or of Roentgen-ray treatment. Our friends, the surgeons, should get over that intolerant attitude that assumes that some one procedure is of divine origin and must be used simply because it is conventional. I object also to the limitation of the expression "surgery" to that form of hand action which uses the sharp knife. The meaning of the word is simply the doing of something with one's hands. Anything that is employed by the hand in hand work for the local destruction of disease or the treatment of the patient is surgery, even if it is not cutting with steel, and if it produces a better result than some other kind of surgery in a given instance it is good surgery. We want to select the best way to deal with these cases and to remember with open-mindedness that different agencies are required for different phases of the disease even in the same patient.

Dr. Kennon Dunham, Cincinnati: As Dr. Pusey has said, roentgenotherapy is falling into disuse through being handled by untrained men and with improper technic. Papers of this kind which deal with technic and refer to results obtained and substantiate these results by photographic proofs before and after treatment tell the tale better than any amount of writing. Men who have been getting results have been paying much attention to the technic of this work.

Dr. J. M. King, Nashville, Tenn.: The doubt as to the efficiency of the Roentgen ray in the treatment of carcinoma should be wiped out in a body of experienced physicians. Since 1904 I have used the Roentgen ray and my results will parallel those of Dr. Pusey. At first I used small doses, but I have from my own experience increased the mass of the dose, giving only six or eight exposures, or maybe less, in the average-sized epithelioma. I should like to ask Dr. Pfahler to give his technic in treating sarcoma of the bone.

Dr. A. M. Cole, Indianapolis: The massive-dose method has many points of merit, but I have been deterred from using it because of my very strong belief that we do have patients who show an undue susceptibility to the effects of the ray. I know that there are some workers in this field who have come to believe that this is not true; but in my experience I occasionally find a patient in whom a half or third of an erythema dose will bring about a marked dermatitis. For instance, in the last month I have treated a young lady for a lesion on her hand, and after two treatments with the fractional dose method, which I use, she developed a very painful dermatitis. The average patient could have taken eight or ten such treatments before showing the slightest erythema. It does not make any difference if we get a marked dermatitis in treating cases of deep carcinoma or epithelioma, but in skin diseases such as acne, eczema, etc., the massive-dose method, followed, in a susceptible patient, by a severe dermatitis particularly about the face, might be a very serious matter. This objection will always, in my mind, limit the use of the massive-dose method, given at one sitting, to cases of carcinoma and for depilation.

Dr. W. A. Pusey, Chicago: I sympathize thoroughly with the scientific ideals which attempt to determine the limits of physiologic safety of Roentgen-ray exposures, but up to the present time I have been constrained to hesitate about adopting the maximum-dose method in my practice. I have done this for three reasons. First, I am sure that I have had my best therapeutic results by a technic which consists of fractional doses, not of a few heavy applications. Certainly in my experience the attempt at a radical quick dose has not proved as therapeutically efficient as several cumulative doses. In the second place, I cannot get away from the feeling that we are running a considerable amount of danger in the use of massive doses. We can make all of our factors the same except one, and that is the factor of the individual, the personal equation of the patient. At any rate, I do not feel that one patient will react just as the next one will. If I can draw any conclusion from my experience it is that there is a difference of susceptibility in patients. In the third place, to give a massive dose requires attention to a group of important factors, and I think that in routine work the danger of some error is not to be overlooked. As a matter of fact I have been consulted to-day about a burn following a massive dose of Roentgen rays for destroying ringworm, so that the idea of danger is not purely a theory. As for my technic I give repeated doses of Roentgen rays until I produce my effect.

Dr. G. E. Pfahler, Philadelphia: I agree with Dr. Lange that the massive dose is the ideal dose and the nearer we approach it the nearer we approach the ideal, but it is also a more difficult thing to give, requires much greater skill and involves a much greater risk, so that if we want to be on the safe side we had better stick to the small doses. I myself work toward the massive dose, but I do not attempt to give the complete treatment in one dose. I do not treat epithelioma, as I did originally, however, with twenty-five or thirty applications, but give from three to six; in other words, I approach the massive dose as nearly as I can with safety. I believe that there is a certain amount of individual susceptibility, but I believe a great deal of the supposed susceptiblity is due to the variation of the tube used.

Dr. Sidney Lange, Cincinnati: I appreciate that our units of measurement are yet imperfect and subject to variations, and that brings in the factor of the manufacturer, just as it is brought in by the variation in pastils or bromid paper or whatever meter we may use to measure the dose. I still believe, however, that, if the technic is mastered, the results are very much better with massive than with the fractional doses. I looked idiosyncrasy up some time ago and read all the literature I could possibly find on the subject, and in the report of the committees the consensus of opinion was that what we consider to be idiosyncrasies on the part of the patient are variations in technic, that a Roentgen-ray tube is a very much more unstable thing than the patient and that, while we may think we are repeating our technic from day to day, there are certain variations in the filter or the tube used, and in the susceptibility of the part of the body treated. When I produced burns the trouble was not due to idiosyncrasy on the part of the patient, but was due to the variation of the technic, and although I thought that I was repeating my technic I was not. Formerly I was gaging indirect methods instead of using a direct method of measurement. I feel sure that I have accomplished results with massive doses that I have never been able to accomplish before. If you give repeated small doses in alopecia you run the chance of atrophy. It is like wanting to dissolve a gumma with potassium iodid and giving 5 or 10 grains a day, whereas to accomplish this result it might require 100 grains a day. You must also use massive doses of the Roentgen ray to treat ringworm adequately. I can only point to the results obtained by those who are treating large numbers of children with massive doses and getting good results. The German gynecologists could never have accomplished what they are accomplishing now in the treatment of uterine myomas if they were not bold enough to use the massive dose. Five or even two years ago the exposure of a patient to 1,000 units of the Roentgen ray would have been considered criminal, yet, with proper precautions, desensitizing the skin by such massive doses, it has been possible, for instance, to cause the atrophy of the ovary in several sittings, as in Krause's clinic in Freiburg. In the treatment of myomas the percentage of cures with massive doses is much higher than with fractional ones.

Dr. George E. Pfahler, Philadelphia: Someone asked me to describe more fully my technic. The technic is described in the body of the paper in more detail. I should like to emphasize one point in deep therapy of all kinds, particularly of sarcoma of the bone: probably the most important single factor to be watched is keeping the tube hard. The operator is apt to let the tube run down after it has been used a minute or two, in which case skin effects instead of bone effects are produced; the very soft rays instead of the hard rays are utilized.

Dr. Kennon Dunham, Cincinnati: Do you find it necessary to change the tube during a Roentgen-ray treatment?

Dr. G. E. Pfahler, Philadelphia: Whether I change the tube or not depends on the existing instrument. If I use an instrument generating 1 milliampere of current I can use the same tube during the whole treatment. On the other hand, I have used as many as a dozen tubes in a single treatment with the bigger machines. There are a great many points in the technic that have to be adapted to the individual apparatus. I therefore try to stick to principles rather than to give specific details, which will vary with the operator.

THE MINIMIZING OF INSANITY *

MARY LAWSON NEFF, M.D.
FAIRFIELD, IOWA

When we consider that the number of students in all the colleges and universities of the nation is exceeded by the number of patients in our hospitals for the insane; that the annual economic loss is conservatively estimated at $100,000,000, to which may be added one-third as much for actual maintenance; while the burden of sorrow and loss in social and ethical ways cannot be computed, we realize that in seeking to minimize this sad feature of our national life we are considering no small problem in medicine, in sociology, in economics and in philanthropy.

Obviously, the first consideration is, how far is it possible, with our present knowledge of preventive medicine, to decrease this number.

At least from 15 per cent. to 20 per cent. of commitments are attributed to alcohol, and from 10 per cent. to 12 per cent. to syphilis. Such cases are, in theory at least, preventable; and we can fairly hope for a marked decrease in these groups as a result of education. If, however, we consider alcoholism itself as a symptom of the neuropathic make-up, and give some weight to the suggestion that paresis develops only in the subject of syphilitic infection in whom the nervous system forms the line of least resistance, we will be inclined to draw conclusions with some degree of caution.

A small group of cases following acute infections, or due to various forms of chemical poisoning, may be added to those having a known and preventable cause.

The number of patients doomed to unavoidable insanity by heredity is difficult to estimate. Massachusetts gives 21 per cent. of admissions as having "markedly poor heredity." The psychopathic hospital of the University of Michigan reports a hereditary factor in 60 per cent. of admissions.[1] Here we have a problem for eugenics.

And to the statesman we refer the problem of immigration. For the national unwisdom of importing as ancestors of our future citizens aliens who furnish a percentage of insanity twice that furnished by our own people, there is no adjective available.

In the preventable cases of insanity, however, the patients, for the most part, either recover, or live a comparatively short time after commitment; so that, while they constitute perhaps one-third the number of commitments, they contribute only a small part of our permanent institutional population. Hospitals for the insane are filled with the accumulating cases of dementia praecox, of the manic-depressive insanities, and of the large group of unclassified psychoses. The underlying somatic causes which produce mental symptoms in these groups we do not know, and it is idle to talk of prevention, in a strictly medical sense.

Here is a great field for medical study, and the work already done is absurdly inadequate. In bio-chemistry, with its problems of metabolism, of auto-intoxication, of anaphylaxis, the field has hardly been touched; and little more can be said of the bacteriology of insanity. Even empirical methods of treatment have not been fairly tried. Who can say what would be accomplished by treating insane patients thoroughly and persistently with open-air life, measured amounts of water, purin-free diet, maximum elimination, and interesting occupations suited to their mental conditions—and combining all these forms of treatment in one question?

---

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-Fourth Annual Session held at Minneapolis, June, 1913.

[1] Report for biennial period ending June 30, 1911.

When we reflect that every form of insanity with a known cause, is due either to a bacterial or a chemical toxemia, is it not fair to assume that we must look to general medicine for further light on our problem, and to question the psychiatry which is not an integral part of general medicine—especially that which has for its postulate *"Mens insana in sano corpore."*

Bossi[2] has criticized the larger German institutions for the insane because no specialist for internal medicine is included in the staff, and in this respect at least we would do well not to model our American institutions after them.

From the work of the various social agencies we may expect some valuable help in caring for paroled patients, in assisting borderline cases to maintain themselves outside of institutions, and in rendering permanent some recoveries in patients, who, without after-care would not find a safe environment. The "consulting psychologist" may also in time come to be a factor in enabling people of neuropathic inheritance to avoid the dangers of stress.

From the advent of the psychopathic hospital we hope much: yet we cannot ignore the possibility that its various functions as an observation ward, a medical research laboratory, a psychologic experiment station, an institution for the clinical teaching of medical students and a receiving and distributing depot for large numbers of patients, may overshadow its function as a hospital in which real therapeutic work shall take precedence of everything else. The publicity and confusion incident to some of these functions, indeed, make the best kind of therapeutic work difficult. It is interesting to know, in this connection, that the Psychopathic hospital at Syracuse, N. Y., reports that the number of commitments from that county remains stationary, while the population increases. This is not true of the surrounding counties in the same hospital district. It is also interesting to note that 40 per cent. of the patients admitted to this hospital, do not need to be committed to state hospitals. At Ann Arbor the percentage committed is even smaller.

MINIMIZING THE DEGREE OF INSANITY

But there is quite another sense in which insanity can be minimized. We have been considering our problem quantitatively. Let us also consider it qualitatively, and ask the questions, "How far can the degree of insanity be minimized? How much of the mental deterioration to which we have become accustomed could have been prevented?"

As institutions have multiplied and increased in size, they have been compelled to depart farther and farther from the "protected homes" that apparently formed the earlier ideal of care. That inhuman thing that is connoted by the term "institutionalism" has brought about conditions under which none of us could remain normal.

From the following incident my own vital and personal interest in an effort to normalize the life of the insane dated. Passing through a ward where flowers, sunlight, air and pleasant furnishings gave a superficial appearance of comfort, my attention was called to the patients. These were sitting on either side of the corridor in straight rows, interrupted here and there by a potted plant, or by a "sacred" sofa pillow on which human head had never lain. This row, the chairs all alike, and the faces all turned the same way, left nothing to be desired from the standpoint of geometry. With hands folded, often with eyes closed, not one of these people showed any gleam of interest in life. I stopped to speak to a sweet little white-haired woman, saying, "Why don't you people find something to do? Can't you play games, or read aloud, or something? You can at least break up this row, and turn around and talk to each other!" The reply, given in a perfectly colorless voice, was, *"We are not allowed to turn around. The matron thinks we look neater sitting this way."* Then and there I determined to study my problem from the patient's point of view; and as I studied it thus, there grew a deep conviction that the cruelest thing that comes to these thousands of fellow-beings whose lives are spent shut away from the world, is ennui—the unspeakable ennui of hours and days and months and years, colorless beyond anything we can imagine.

Normal life is largely a series of responses to the three stimuli furnished by necessity, ambition, and the family affections. Kant expressed this when he said: "A man to be happy must have something to work for, something to hope for, and something to love." The institutional patient has no necessity—there is no need for him to earn his daily bread. He has nothing to gain that stimulates hope, no opportunity to improve his condition, or one so trifling that it cannot be called an incentive. He has no loved ones to care for and serve. He is suddenly and effectively cut off from the motives that actually make life, and in this abnormal environment, already abnormal himself, we may expect, and we certainly find, that after a time we have a mental condition that is a blend of the original psychosis and the "psychosis of abnormal living." The patient becomes a sort of human palimpsest, and only the mental archeologist could say how much of that which can be deciphered is of the original writing.

THE REACTIONS TO ENNUI

There are four main reactions to prolonged ennui—reactions that are not an essential part of the insanities, but such as would occur with ourselves if similarly placed. The most common one is apathy—a gradual subsidence into a dull vegetative existence, an "acceptance of cold-storage life," as a superintendent once expressed it, giving to pathos the whimsical garb in which we often clothe it. A second reaction is violence. The patient to whom apathy is temperamentally impossible, finds some outlet for his energy, and some relief from being bored, in breaking a window, or screaming, or giving an attendant a black eye. The "disturbed" patient is more frequently the result of our methods of care than the occasion for them. A third reaction is untidiness. The unoccupied mind centers itself on physical sensations, and picking at the skin, spitting, pulling out hair, and all the familiar habits of the "untidy" ward become fixed. The fourth reaction is the elaboration of delusions, fears and obsessions, until the normal possibilities of the patient are lost in perverted mental activities that obliterate everything else.

The great majority of patients in hospitals for the insane who have not been kept busy and contented will fall into one of these four classes. The problem, then, is to find normal stimuli, incentives, rewards, and human reactions for people whose horizon is contracted, and whose mental life is less normal than our own—though no such gulf exists between the sane and the insane as is usually assumed. Only by treating the insane just as we ourselves would wish to be treated, will practical and effective ways of helping them be found. The "normal areas" of the patient's mental life are the ones on which to base his treatment, rather than the abnormal ones.

---

[2] Wien. klin. Wchnschr., Nov. 21, 1912.

Since we cannot avail ourselves of the major stimuli of life, we must utilize to the fullest possible extent the minor ones. All forms of self-expression should be developed in an institution, using the play-motive as largely as possible. Play has been truthfully called the greatest educational agency that exists. In normal life years of play precede and prepare the way for work. By the same path the patient with the mental status of a child may best be led to more serious forms of employment. Every method of stimulating ingenuity, inventive ability, aesthetic work, or self-expression of any kind, should be employed. Love of approbation is a fundamental emotion, which is not lost even in marked dementia, and this can always be utilized. Altruism can be developed to a degree surprising to any one who has not actually attempted the work.

I once saw a group of discontented patients transformed by "adopting" an orphan asylum for whom hundreds of little garments were made. In another hospital a society of patients calling themselves "The Helping Hand" spends certain afternoons working for the less fortunate wards—preparing material for the teacher who reeducates deteriorated patients; making hoods and slippers for the tuberculous ward; mittens for the men who shovel snow—acting, in short, like ordinary human beings. Recently a group of patients packed a box for Dr. Grenfell's work in Labrador, taking great pleasure in filling it with articles made by their own hands.

The activities furnished for patients should be as normal as possible in every way, including carefully adapted methods of teaching, a variety of work, liberal provision for recreation, respect for the "personal equation," reward for the work performed, and a "therapeutic disposition of the product." After a patient has done his or her fair share of the institutional work, some part of each day should belong to the patient. Monotonous and unremunerative toil is not therapy. A patient who has always estimated the value of labor in dollars and cents should be allowed the privilege granted to the convict in the more progressive states, of receiving at least some small share of the money value of his labor. If we say to a patient, "You are a human derelict, supported by the state, and all that you can earn belongs to the state," we can hardly expect as a reaction the interest and pleasure that is the essential part of mental therapy.

THE INDUSTRIAL STATUS OF THE INSANE

In an admirable discussion of the rights of inmates of penal institutions, Lyon[3] questions "the assumption that the delinquent has forfeited his industrial status." The assumption that the unfortunate patient with mental symptoms, who is entitled to sympathy instead of discipline, has "forfeited his industrial status" would hardly seem tenable. Prof. C. R. Henderson of the Department of Economics in the University of Chicago, expresses admirably the proper point of view in this regard by saying, "What should be the patient's occupation, and what should be the disposition of his earnings should be determined by medical authority, with sole reference to its effect on his health." As the wide-spread movement in the field of occupational therapy increases, this question of the wise and proper disposition of the products of the patient's industry becomes an increasingly important one. It has been dwelt on at some length because widely varying views are held, and actual cases of transforming what should be a therapeutic measure of the greatest value into a mere exploiting of a defenseless class of people have not been lacking.

The economic gain in transforming the violent patients into tractable ones, the untidy into neat ones, the destructive into productive ones, and the unhappy into happy ones, which follows a well-planned occupation movement, is very great, even where patients are given, as is done in some institutions, all the proceeds from such work as can be sold. In visiting some sixty institutions for the care of the mentally abnormal I have noted repeated examples of this economic value of proper occupation. This is perhaps not of the first importance to the physician, but it is of the greatest assistance to us in seeking the legislation on which we must depend for future advance. One instance recalled was the transforming of four "disturbed" wards, under the supervision of a skilful and devoted physician, into three quiet, cheerful and industrious halls, with a residue of disturbed patients in the fourth hall only. Thirteen nurses now do the work performed before this transformation by seventeen.

In another hospital the occupation department, under a competent teacher and a wise superintendent, is admirably managed in this way. Each patient is asked to do half a day's work for the institution, without reference to whether his maintenance is paid or not, as his share in the community life. The other half day is his own, and in this time opportunity is given to join one of the occupation classes. If a basket is made or a rug woven that sells for a dollar, half of this goes to support the occupation department, in purchasing materials, paying the teacher's salary, etc.; while the other half is credited to the patient. If, however, he has been unwilling to do his share of work for the community, half his earnings go into a special fund for the working patients who are unable to earn a little spending-money. This plan appeals to the patients' sense of fair play, brings about loyalty to the institution and is, in the best sense of the word, economic.

The beginnings already made in this wide-spread movement to provide a life as nearly normal as possible for the insane, and to prevent for the future gratuitous mental deterioration, are so fruitful and encouraging, that we may hope for much greater results within the next few years. What may ultimately be accomplished, no one can yet say, but we may hope soon for a day when the invisible motto now lettered over the door of our hospitals for mental patients, "From him that hath not shall be taken away even that which he hath," shall fade, and the institution for the insane shall be a protected community of people living as normally as possible.

ABSTRACT OF DISCUSSION

Dr. Pauline M. Townsend-Hanson, Marshalltown, Iowa: As a medical student, I spent a summer in the infirmary of the Pennsylvania Hospital. Never have I forgotten, and so long as I am able to be active never shall I forget, the many impressions carried with me from the infirmary of the insane asylum. No system was planned for employment of the patients and, outside of the head nurse, none of the attendants in charge had any preparation for the work. Any one who was willing to work could go in and be tried out on the floor, and some of the attendants in the asylum were of a very inferior type. The pay was $15 a month with board and laundry, and attendants who could be secured for $15 a month were inferior in capacity, cultivation and mental development.

---

[3] Jour. Criminal Law and Criminology, May, 1912.

Even these inexperienced attendants recognized that a desire for employment on the part of the patient was a hopeful sign of recovery. We encouraged employment as much as possible, but a systematic method with a person trained for it would have done much more. Work was given to the patients as an experiment, but no effort was made toward remuneration. Some of these patients would knit yards of lace, if we would supply the thread. I felt, however, that I had no right to take the labor of the patient without recompense. I shall be glad to support any move that will help to bring about, as soon as possible, the desired change in our state asylums suggested by Dr. Neff.

Dr. E. S. Everhard, Dayton, Ohio: It seems proper that we discuss the preventive as well as the minimizing side of this question. The point that I wish to bring out is a little different from that brought out in this paper. Before patients are taken to the insane asylum they are in the hands of the general practitioner. In the last year or two I have asked the physicians in charge of several of our insane hospitals what they were learning as to the causes of insanity, and three times I have received the reply: "We can find out nothing about these patients, because we can not get any history. The patient comes to us, often under the care of an ignorant ember of the family or a neighbor, with a well-developed ise of insanity. Neither the patient nor his attendant is eliable and we can therefore get no history worth considering."

When I asked who was responsible for this, who committed the patients, I received the reply that there was only one physician on the board of commitment and that he did not know the patient, as a rule, and could not get the history. It seems to me that the problem is for the general practitioner, who, sometime during the process of the development of this insanity, has hold of the patient and can get the history. I have asked the men in charge of the hospitals for the insane why they did not start some movement by which they could get the history of these cases, and I received the reply that the general practitioner is not interested. I want to make an appeal for the general practitioner. We are all interested in the things we know about. We do not know how to obtain the general history of the patient in such form that it will be of service to the persons in the hospital who take care of these cases. The experience of the Committee for Public Health Education, which I have been connected with for four years, has been that if you want anything of the general practitioner, and tell him what you want, he is interested. Would it be possible to bring this matter in some way before the general practitioner so that he will know in what way he can best help the hospitals to obtain the history of the patient and to gather those statistics which are necessary in order to make a proper study of the cause and prevention of insanity?

Dr. J. N. Hurty, Indianapolis: I have made a superficial study of insanity in our hospitals for the insane to obtain some information in regard to the prevention of this trouble. I have found that 100 per cent. of the patients were great medicine-takers, and it occurred to me that drugs were probably another source of mental poison. I visited the houses of ten insane persons, all farmers' wives, and all were consumers of patent medicine. Alcohol had entered into their insanity, without a doubt, and I do not know to what degree the drugs contained in these patent medicines had affected their cases. Sleeplessness, which, in many instances, is a sign of approaching insanity, had come on them, and for this hypnotics had been prescribed in many cases, and the condition was probably made absolute by these hypnotics. In the light of the investigations made, I conclude that alcohol accounts for fully 25 per cent. of insanity. The effects of constant medicine-taking are also to be considered. Another 25 per cent. seems to be due to syphilis. If alcohol, drugs and syphilis are causes of insanity, we have within our control three important forces which can be checked.

Dr. M. P. Overholser, Harrisonville, Mo.: I wish to emphasize that part of Dr. Neff's paper in regard to the industrial, educational, occupational and diversional treatment of the chronic insane, for I believe that herein lies a most important and yet undeveloped field of work in the treatment and management of a large percentage of the chronic insane confined in our state hospitals. It is true that occupational and various diversional treatment cannot restore that part of the mind which disease has destroyed, but in a large percentage of cases the scraps of a wrecked and shattered mind may be stimulated and reeducated by the vivifying influences of occupation and diversion. We have tried this and know it to be true. Several years ago the legislature of Missouri granted one of the state hospitals a special appropriation for the construction of an industrial building. This building was fitted up so that we were able to place a large number of the patients at work in the manufacture of mattresses, brooms and brushes of various kinds. The women patients are taught to make numerous articles of wear and ward supplies, such as dresses, bonnets, men's shirts and overalls, carpets, rugs, quilts, etc. In addition to this, we added in March, 1912, another department called the art or occupation department, with a woman instructor, who teaches the women patients raffia weaving, brass craft, cross-stitch, French and punch embroidery, crocheting, drawn and hemstitch work, weaving bobbin lace and Navajo and other rugs, making artificial flowers and a number of other things too numerous to mention, to which can be added from time to time new and novel diversions in the way of occupation. The monotony of the occupational treatment is broken every two weeks by a tea party, at which fifty or sixty of the women patients meet in the occupation room dressed in their best gowns and listen to music, play various games or busy themselves with needlework and partake of refreshments. Every four weeks a large number of the patients, male and female, with nurses, attendants, employees and officers, meet in the chapel to play cards, checkers, dominoes, flinch, jack-straws and other games. The beneficial effects of these methods of treatment on the attitude, disposition and general demeanor of many of these patients are remarkable, and I therefore wish to emphasize the importance and necessity of increasing this kind of work in our state institutions for the insane, for I believe that no more powerful therapeutic agent can be found in the treatment of a large percentage of the insane.

Dr. S. A. Knopf, New York: My work with tuberculosis takes me occasionally into insane asylums and I have had occasion to observe some of their peculiar features. I have not made so thorough a study as Dr. Hurty has of the etiology of the disease of these and other unfortunate sufferers from mental affliction. He says that 100 per cent. of insanity is due to drug-taking. This is a very large percentage; I wonder how he came to this conclusion.

Dr. J. N. Hurty, Indianapolis: I followed out the cases of ten women and they were drug-takers—patent-medicine takers.

Dr. S. A. Knopf, New York: I believe that the humdrum existence of the farmer's wife in far outlying districts and isolated regions is more responsible for insanity among these poor women than drug-taking. I wish to emphasize what Dr. Hurty says concerning syphilis, but I wish to go a little further. We have many forms of insanity which have never been considered as of syphilitic origin until recently; that is to say, until Noguchi of the Rockefeller Institute found in the brains of many persons who had died in the asylums the organisms productive of syphilis. Antisyphilitic treatment has been inaugurated in many cases with good results in which there were no outward syphilitic symptoms. I am convinced that many of our defective children owe their infirmity to a syphilitic transmission; hence, let us not be afraid, when we are in the presence of the mentally defective child, to apply the Noguchi or Wassermann tests. You will be surprised at the number of times you will find evidence of a syphilitic transmission. As a measure to diminish insanity among the workers, let us appeal to the employers, the great industrial proprietors, the great philanthropists, to inaugurate a welfare movement among their employees, increasing the hours of rest and recreation. The man or woman constantly doing the same thing for twelve or fourteen hours, six days in the week, and sometimes for six and a half days, is apt to become mentally depressed and even insane. It is this humdrum existence of so many of our industrial employees which leads directly to the insane asylum, or indirectly through alcoholism. Let philanthropists inaugurate also some sort of pleasant diversion among farmers, the toilers of the soil in isolated regions, and insanity among them will diminish. Insanity is as much a social problem as a medical one, and if the social conditions of those liable to become insane are improved their number in the asylums will surely diminish.

Dr. A. W. Erskine, Cedar Rapids, Iowa: Six years ago it was my privilege to be associated with Dr. Neff in the institution where she first started her work in the normalization of the life of the insane, and I am familiar, therefore, with some of the difficulties of her work and some of the discouragements met. The occupation classes were known from one end of the hospital to the other by nurses, attendants, and, I am sorry to say, a large percentage of the staff, as "booby classes," and ridicule was heaped on them. I appreciate the courage that has permitted this work to be carried on in spite of the ridicule, unjust criticism and opposition that it has had to contend with. I believe that it is due to a few pioneers in this line of work that the care, education and treatment of the insane is gradually being brought out from a chaos of empiricism and put on a rational basis.

Dr. Bertha Van Hoosen, Chicago: I want to give a little bit of ancient history and a tribute to Dr. Palmer of the Michigan Insane Asylum at Kalamazoo. Twenty-three years ago I had the pleasure of being one of the assistant physicians in the Kalamazoo Insane Hospital. Whenever Dr. Palmer went to Chicago to buy clothing and materials for the patients, he made it his business to buy as though for individual cases. No patients were allowed to have dresses, shawls, hats, or any article of clothing alike. On the day that he returned, the patients were invited to go and choose their dresses, as they would go to a store. I never saw a patient put under restraint in that hospital.

The patients were all employed in the most natural sort of way. When they were dements and could be taught hardly anything, they were still able to draw the mops across the floor. That was the most practical and simple sort of exercise and employment. The patients also worked in the kitchen, in the dining-room and in the laundry; there was absolutely no department that was not filled with patients and they had a chance to choose the kind of occupation. Every day they were allowed to go out and take exercise; sometimes two and three times a week we had a fine entertainment. Teachers passed into the large chapel in which Dr. Palmer took so much pride; in fact, just after I left, he built a new chapel, in which the rooms were so arranged that the neurotics could be separated from the other patients and yet attend these entertainments, which they of all classes seemed to enjoy most. More than all that, every assistant physician was trained to make it his business to get into the lives of his patients. I had a certain number assigned to me and all the letters from relatives were turned over to me to answer; these letters were inspected by the superintendent and criticized; we had to find out in this way what the patient's home and surroundings were and what the patient's tastes were; in fact, it would take me a long time to tell the number of ways in which the patient was considered as an individual in the Michigan State Asylum so many years ago.

Dr. Mary Lawson Neff, Fairfield, Iowa: I know that there are hospitals here and there that have always maintained a high grade of humane work. One good point brought out in the discussion is that there are some persons who will remain sane, or stable enough to maintain themselves in society in a certain environment, who will become insane in a different environment. There is a great task for the medical profession in educating these people of neuropathic make-up.

Dr. Everhard spoke of the difficulty of getting a good history. Patients come to an insane asylum often after having been sick for years. They have had headaches, insomnia, mental depression, attacks of rheumatism, gout, neuralgia, eczema, all sorts of symptoms of a gradually increasing toxemia; but the general practitioner who sends them is apt not to take the trouble, or does not consider it important, to send a good history of the patient's physical condition preceding the development of mental symptoms.

This prolonged toxemia would give other indications, especially changes in the kidney. The reports of post-mortem examinations at the State Hospital at Norristown, Pa., were analyzed with the following result: The insanities without assigned cause (below the age of 60) were tabulated for a period of fifteen years. This covered the services of five pathologists. These cases, at necropsy, gave 90 per cent. of chronic interstitial or other form of nephritis. This must mean that we have a tremendous factor of a toxic nature. Many other things point to the same conclusion, and make this early medical history in a case of insanity of great importance.

PRECOCIOUS MENSTRUATION *

F. P. GENGENBACH, M.D.
DENVER

The term "precocious menstruation" should be limited to cases of more or less periodical menstrual discharge occurring in children before its usual appearance at the age of puberty (before the age of 9 or 10 years—Schauta), and should not include cases of hemorrhage from the vagina occurring within a few days after birth and not recurring subsequently.

Precocious menstruation is usually accompanied by signs of precocious maturity, i. e., "the premature development of the whole organism concurrently with menstruation and ovulation" (Morse[1]); or, in other words, "precocious menstruation with an early appearance of the external manifestations of puberty" (Croom[2]). These cases are by far the most interesting, and my case is of that type.

REPORT OF CASE

History.—Baby X., aged at time of examination 2 years (January, 1913). Adopted shortly after birth, at which time a Wassermann proved negative. History of parents unobtainable except that father was a Jew, mother an American. Labor normal. Weight at birth about 6½ pounds.

Bottle-fed, with modified milk. Weight at 1 month, 7 pounds; 2 months, 8¼ pounds; 3 months, 9⅜ pounds. At this time there was a severe gastro-intestinal disturbance with temporary intolerance for cow's milk. A wet-nurse was employed for several weeks, and then a weak milk modification. Weight at 4 months, 10¾ pounds; 5 months, 12 pounds; 6 months, 13⅞ pounds; 7 months, 16⅛ pounds; 8 months, 17½ pounds; 9 months, 21⅜ pounds.

The first tooth erupted at 10 months, at which time the menstrual flow first appeared, lasting three days. The discharge was of bright red blood from the vagina, with slight menstrual odor. At this time the child seemed rather large for its age, but no other signs of precocious maturity were noticed. Menstruation recurred at intervals of from one to three months, most frequently at intervals of six weeks. The child menstruated eight times in fourteen months. For a few days before periods a slight leukorrhea was noticed; the child was rather cross and acted as if in pain. She walked at 17 months after braces had been applied to support the limbs.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

[1] Morse, John Lovett: Precocious Maturity, Arch. Pediat., 1897, xiv, 241.

[2] Croom, J. Halliday: Premature Menstruation, Allbutt's System of Gynecology, 1906.

First Examination.—Large, well-developed, healthy looking child. Skin dark and hair very curly (Jewish type). Mentally bright for her age. Chest and abdominal examination negative as regards internal organs. Weight 38 pounds; height 37 inches; 17 teeth; circumference of head 19 inches; chest below breasts, 21 inches; across breasts, 22½ inches; abdomen at navel, 22 inches; breasts very prominent, about size of half an orange; nipples well developed, with slight areola; a few hairs around nipples; hair quite noticeable in the axillae, and pubic hair very noticeable; mons veneris and labia very prominent; hymen well developed, the opening admitting the tip only of the little finger, preventing a digital examination of pelvic organs. Rectal examination objected to, and photograph not obtainable.

Second Examination.—Age 28½ months. The child had menstruated four times in four and one-half months. Menstrual flow seemed to be increasing both in quantity and duration, and the peculiar menstrual odor was very marked. The child must wear napkins during a period of about a week. Leukorrhea was increased, being present most of the time. Weight 41½ pounds; height 39 inches; 18 teeth; circumference of head, 19 inches; chest below breasts, 21¼ inches; across breasts, 23 inches; abdomen at navel, 22 inches; pelvis, 23 inches. The breasts were noticeably more prominent, as also the growth of hair under the arms and about the external genitalia.

OTHER CASES

Lenz[3] reports in tabulated form 130 cases of precocious menstruation, dating back over 100 years. In addition to the case just reported I have found the following references to cases apparently not included by Lenz.

Raffaelli[4] reports a case, D. E., aged 4½ years, menstruating for several months, lasting about eight days, preceded by abdominal pains. Height, 1 meter, 10 cm., weight, 19 kg., and average build of a 6-year-old girl. No syphilis, alcoholism or other hereditary disease. Hair in axillae, mammary areola very noticeable, but no enlargement of the mammary glands. Mons veneris prominent and covered with hair about 1 cm. long. Labia very much developed, resembling those of a girl 10 or 12 years old. Hymen well developed and the opening therein permitting introduction of tip of little finger. No evidence of pelvic tumors.

In his article Raffaelli refers to the bibliography on the subject in the work on Children's Diseases by Grancher and Comby. He also refers to a number of similar cases, most of which are included in Lenz's tabulation. The apparent exceptions are as follows:

Reim: The case of a girl 6 years old, who menstruated at 5 years; physical signs of puberty of a girl 13 or 14 years old. Abdominal examinations revealed presence of an ovarian cyst.

Woodruff[5] reports a case of a girl 6 years and 2 months old who menstruated at the age of 2 years. She was developed, apparently, like a girl of 12 to 14 years.

Barband and Lefevre[6] report a case of Puech of a girl who menstruated at the age of 4 years. When 8 years old she had sexual intercourse and miscarried at three months.

Dotti[7] at the meeting of the Tuscan Pediatric Society in 1908 presented three cases of 8, 3 and 2 years. These three cases were the only cases noticed out of 6,000 patients during a period of two years at the Pediatric Clinic, Florence, Italy. In one of the three cases the important factor was a suspicion of hereditary syphilis (premature birth, mother advanced in years). In all three the general body development was above the average, with psychic deficiency. One of the girls had a marked development of the thyroid.

In the discussion of Raffaelli's case, Professor Mya cited a case of precocious puberty seen by him in a girl 4 years old, and Dr. Funaro, a case of precocious menstruation that he had seen at the Charité in Berlin, in a girl of 5 years. It is possible that this is the same case seen by me at the orthopedic clinic of Professor Hoffa in 1908, at which time the following notation was made:

> Girl nearly 5 years old has menstruated almost regularly since 7 months old. Precocious physical development first noticed when about 1 year old, and from that time has grown very rapidly. Breast, pelvis, external genitalia and body growth that of a girl 10 or 12 years old. Hair in axillae and pubic hair very noticeable. Intelligence about normal for age. Comes to clinic for left-sided coxitis. Cast applied.

Raffaelli observes that "Many of the cases present pathological conditions such as tumors, abnormal development of the thyroid, suspicion of hereditary syphilis, rickets, obesity, hydrocephalus, adenoids, psychic deficiency, etc." He further observes that "According to some authorities, beside the climate, the altitude, the proximity of the sea, country or city life, the social condition, the color of the hair, the mode of living, education and race would seem to have a certain influence on menstruation; in fact, it is proved that the Jewesses menstruate before many other women (the Slavs for instance) who live in the same climate."

The fact that these cases are a source of embarrassment and worry to the parents, as well as to the children themselves when they become old enough to appreciate their condition, ought to be reason enough to bring up the question whether anything can be done to control the condition. Glynn[8] refers to two remarkable instances of sexual development in children with a tumor of the ovary (Lucas[9]) and of the testicle, respectively, in whom "The former childlike appearance returned after the removal of the tumor." He also refers to seventeen examples of sex abnormalities in children associated with adrenal hypernephroma verified post mortem, the abnormality in most of the cases being of the type of precocious maturity. He further speaks of the relationship of the pituitary gland to the adrenal gland and sex characters; also of the pineal gland and sex characters. Thus he says "tumors in the pineal region, though rare, are occasionally, like those of the adrenal, associated with changes in sex characters, particularly true precocious sexual development.

Congenital hypertrophy of the pituitary gland is frequently associated with giantism and congenital hyposecretion with infantilism (Glenn[10]). There is probably also some relationship between the ovaries and the thyroid gland.

THE USE OF BLOOD-AGAR IN THE ROUTINE EXAMINATION OF MILK SEDIMENTS *

F. W. HACHTEL, M.D.
BALTIMORE

With the ever-increasing evidence of the relationship between milk and the spread of various infections with members of the streptococcus group, methods for their detection in milk and for distinguishing the different types present have been devised.

The direct examination of the stained sediment, originally employed as a means of discovering inflammation of the udder, has been used in an attempt to separate pathogenic and harmless streptococci. Thus, Lewis[1] differentiates these organisms according to the length of the chain and irregularities in the size of the individual cocci. Ruediger,[2] however, believes that these are unreliable grounds of distinction, while Heinemann,[3] Miller,[4] Hiss and Zinsser[5] and Jordan[6] all state that it is impossible to differentiate with any certainty nocuous from innocuous types. Surely it may be stated that the bacterioscopic method is unsatisfactory for this purpose.

Attempts have also been made to distinguish between varieties of the streptococcus by the agglutination test, but these, too, have been failures, heterologous strains often reacting better than homologous.

Following the discovery of Schottmüller[7] that *Streptococcus pyogenes* grows as small hemolytic colonies on blood-agar, this medium has been used to separate the members of the group. The results seem to have varied somewhat; thus, Müller[8] often found milk streptococci as hemolytic as *Streptococcus pyogenes*. Ruediger,[2] on the other hand, studied thirty-five strains of streptococci obtained from milk and concludes that *S. lacticus* can be distinguished from *S. pyogenes*, as the former grows in the form of green colonies with little or no hemolysis.

My first experience with the use of blood-agar in the examination of milk was in the course of the bacteriologic study of an outbreak of septic sore throat. In this investigation the milk sediments were first examined microscopically for pus and streptococci, and those samples that were considered suspicious were centrifuged in quantities of 50 c.c. each and the sediments inoculated subcutaneously into white mice. On the death of the mice, cultures were made from various organs, blood-agar plates being used except in a few instances. In this way I was able to isolate from twenty-three animals 11 strains of *Diplococcus pneumoniae*, one *S. pyogenes* and one *S. epidemicus*. I obtained these two types of the streptococcus, together with the pneumococcus, from one mouse. These organisms were subjected to a thorough cultural study and were found to correspond in all their essential characteristics to the descriptions given of these bacteria.

The work of Ruediger[2] suggested the possibility of still further safeguarding a milk-supply by the use of blood-agar plate-cultures. Following up this idea, eighty-six such examinations have been made. The work so far has been limited to an investigation of the sediment of pasteurized milk and of one which meets all the requirements of a certified milk.

In all cases 50 c.c. of milk were centrifuged from forty-five to sixty minutes, the sediment was mixed with 1 c.c. of sterile physiologic salt solution, and a platinum loopful of this was then inoculated on a blood-agar plate. With a sterile bent glass rod the fluid was rubbed over the surface of the inoculated plate and another one, and the two Petri dishes were placed in the thermostat. After twenty-four and forty-eight hours' incubation they were examined for the presence of colonies characteristic of the members of the streptococcus-pneumococcus group. If present such colonies were picked and their cultural properties studied.

In this way eight organisms have been isolated from seven samples of milk. Four of these were cultures of *S. lacticus:* the colonies of each of these strains were greenish and three of them showed a very narrow zone of slight hemolysis.

Three were pneumococci, these micro-organisms growing as greenish colonies resembling blistered paint. Two strains were pathogenic for white mice. The eighth was a culture of *S. pyogenes;* the colonies were not green and were surrounded by a distinct zone of hemolysis. This streptococcus was pathogenic for white mice.

This streptococcus was not isolated from pasteurized milk, but from the milk of the other dairy previously mentioned. In this case the source of contamination was discovered to be one cow in the herd, which, though showing no physical evidence of udder inflammation, was nevertheless secreting milk containing large numbers of these streptococci. This cow was immediately eliminated from the herd.

The meager number of examinations made precludes the drawing of any conclusions. The results, however, have been sufficiently satisfactory to warrant a continuation of this work. Thus far only pasteurized milk, with one exception, has been examined, but in the future these examinations will be extended to raw milk which microscopically shows excessive numbers of streptococci.

The Reporting of Diseases.—Physicians are occasionally heard to express impatience with the requirements of the law in regard to the reporting of communicable diseases to health authorities. It is obvious that such physicians have given little thought to their responsibilities in safeguarding the public health. Health authorities are ready to attack communicable diseases in their incipiency. Scientific knowledge of the more serious of such diseases has led to the adoption of adequate means of controlling them. But health authorities cannot act blindly. They must deal with the individual case and to do this they must know its location and the circumstances connected with it. It is the duty of physicians to furnish this important information. There can be little question as to the moral responsibility of a physician for the secondary cases resulting from an unreported primary case or for the consequent fatalities.—*Bull. Ohio State Board of Health.*

Therapeutics

THE OPIUM AND MORPHIN HABIT

There are so many legitimate and so many illegitimate "cures" for this habit, that a review of the opinions of a man who has had a large experience in the treatment of these conditions is of value. Dr. George E. Pettey[1] of Memphis, Tenn., has recently presented a book which is well worth careful reading and review.

This article embodies Pettey's ideas of the pathology and the treatment of these drug addictions, which are apparently becoming more and more frequent. He says that the average Caucasian will develop an addiction to opium or one of its alkaloids after thirty days' daily use, and but few of these persons will be able to stop the use of the drug after that length of time by their own efforts. If the drug has been used for three months or more, he finds it almost impossible for the person to stop its use without medical aid.

Crude opium and laudanum taken by the mouth are more slowly absorbed than the alkaloids of opium, and the narcotic impression is less; consequently they may be taken longer than the alkaloids without causing an addiction. Pettey finds also that morphin may be used for a longer time without causing the habit when taken by the mouth than when taken hypodermically. Codein and heroin may be taken for a longer time than morphin without causing the habit, he thinks, because they inhibit secretions less and cause less intestinal toxemia, and therefore less self-poisoning. Of course, it is well known that any narcotic drug may cause a habit if taken for a longer or shorter period, but he recognizes, as has been observed by many medical men, that any of the atropin series may cause a habit, whether it be belladonna, atropin, scopolamin or any other drug that contains a member of the atropin series. In other words, it should be recognized that a person taking morphin and atropin in combination acquires the atropin habit as well as the morphin habit. This is not generally understood.

SYMPTOMS OF THE OPIUM HABIT

The contraction of the pupil is, of course, observed by all, and its inability to dilate properly when light is excluded is well known. Those persons who have the opium habit in any form are usually exhilarated soon after the drug is taken and then depressed later as the effects of the drug pass off. This variability of mood, which perhaps changes several times during a day, is therefore very characteristic, and should place the person under suspicion. During this period of depression the drug habitué is likely to retire to a place where he can administer or take the drug without observation, and he returns, after a time, more or less normal or elated. Some persons in a certain length of time after the drug has been taken become very drowsy and almost sleep while talking. This condition is likely to follow the more or less alert phase. Some persons have a great deal of itching from the drug, especially a tickling or itching of the nose. Others sneeze at the time the action of the drug is passing off, and the sneezing will be inhibited when they take another dose.

Pettey thinks that an indication that a person is taking cocain as well as morphin is that he walks rapidly and in a zigzag manner, shows great nervousness and fidgetiness, is excessively talkative, and has a variable appetite, sometimes eating enormously and again not eating at all. When a patient is excessively restless and moves constantly he thinks that it shows the atropin combination with morphin, and patients who increase the morphin and also the atropin are likely to suffer from insomnia. He also notes that if the atropin is removed in such a morphin-atropin addiction the ordinary dose of morphin causes extreme nausea. In other words, such a patient suffers from the morphin without the atropin.

Pettey thinks it inexcusable to cause the symptoms usually attendant on the gradual reduction of morphin. He also finds it inexcusable to withdraw the opiate abruptly, unless the patient is first prepared for such treatment. Such harsh treatment is not likely to cure a patient permanently. He is also firmly convinced that the more thoroughly the system is cleansed of toxic matter, that is, prepared for the treatment of the withdrawal of the drug, the less fever there will be and the less neuralgic pain.

Pettey believes strongly in the necessity of reducing the toxins in the system, not only those caused by the drug, but also those produced in the intestines owing to the action of the drug; and he believes that these toxins accumulate in the system mainly because there is deficient excretion. This insufficient excretion is largely due to the fact that the intestines are so seriously affected by the narcotic, in their secretions, muscularly, in their nervous supply and in all their nerve centers. He is convinced, therefore, that no ordinary simple catharsis is sufficient, but that not only should the intestines be thoroughly emptied, but that the secretions, also, should be started if possible, the peristalsis activated and the circulatory and motor nerve centers, if possible, stimulated. He therefore administers a combination of drugs that will promote all of these desired effects, and he finds that, if the nerve centers are not at the same time stimulated, the cathartic drugs will cause pain and disturbance without efficient evacuation of the bowels. Pettey also believes that the cardiac depression caused by withdrawing morphin or some other form of opium is largely due to portal and liver congestion. Such congestion, of course, is well known to interfere with cardiac efficiency; or the reverse, which is so generally understood, that cardiac insufficiency will cause portal congestion. If, therefore, he can relieve portal congestion and liver obstruction, he finds that the circulation misses the morphin less.

A general hyperesthesia or hypersensitiveness follows the withdrawal of an opiate from the habitué, and this of course he points out as the natural reaction from a more or less chronic anesthesia due to the drug. He finds this hyperirritability in all parts of the body, evidenced not only mentally and nervously, but also functionally.

The suffering always attendant on the withdrawal of the opiate can be prevented by previous thorough elimination and the administration of scopolamin. The proper use of scopolamin for the few days it is required will relieve pain, induce sleep and prevent the distressing nervous symptoms due to the withdrawal of the opiate. Pettey finds that with this treatment in two or three days after the withdrawal of the opiate there is no craving or desire for the drug, the appetite returns, the patient will sleep many hours at a time, and convalescence becomes rapid.

"The dose of scopolamin ranges from 1/300 to 1/50 grain at intervals of from thirty minutes to six hours, depending on the individual." Of course the smaller doses should at first be administered until the tolerance of the patient is determined. The frequency is determined by the production of sleep and the freedom from pain. After this condition is produced the drug should be given at such intervals only as are necessary to keep the patient comfortable. In the use of this drug the patient should always be individualized. There is, and can be, no rule as to the dosage or the frequency, but the withdrawal of the opiate should not be allowed to cause suffering, and this drug will prevent it.

---

[1] Pettey, George E.: The Narcotic Drug Diseases and Allied Ailments, F. A. Davis Company, Philadelphia.

PREPARATION OF THE PATIENT

The patient should first receive some hydrotherapeutic treatment, the intensity of which is determined by the patient's strength, perhaps only a tub-bath, followed by a vapor-bath. He should be made to drink a large amount of water in order to wash out all surplus metabolic products that it is possible to eradicate by the urine; but it should be remembered that bile and bowel-discharges are nine times as toxic as the urine, and that urine is fifty times as toxic as the perspiration (Bouchard), and that the principal elimination of toxins, must therefore be from the bowels, and purgation is of primary importance. The cathartic combination found most valuable by Pettey is the following:

℞ Calomel ....
Powdered extract of cascara......āā gr. x
Ipecac ....gr. I
Strychnin nitrate ....gr. 1/4
Atropin sulphate ....gr. 1/50
M. et fac capsulas 4.

Sig.: One capsule every two hours until four are taken, preferably at 4, 6, 8 and 10 p. m., and only after having abstained from dinner and supper on the day on which they are taken.

The treatment may be begun at 4 p. m. with one capsule; the last dose is given at 10 p. m. The patient receives his opiate in his usual dose up to 8 or 10 p. m., but none from that time until after the bowels have thoroughly moved the following morning. Pettey thinks it is advisable that six or eight hours after the last capsule has been given, namely, at 10 p. m., the patient should receive 1/20 grain of strychnin hypodermically, this to be followed half an hour later by 2 ounces of castor oil or a bottle of citrate of magnesium. "Both the strychnin and the oil or saline should be repeated at intervals of two hours until the intestinal canal has been thoroughly emptied." The patient receives no morphin or narcotic during this period. When he has gone as long as he can without discomfort and begins to feel the need of the drug, it should be given him in reduced doses, and it will generally be found that two-thirds of the usual dose perfectly satisfies his system. This reduced quantity should be given at the same intervals at which the patient has been having his morphin before the treatment was begun. After purgation is completed, the patient may be allowed a liberal diet until within six or eight hours of the time of giving the next course of purgative. Forty-eight hours from the time of the first purgative course the second course should be given, consisting of the same ingredients. As stated before, after the first purgative action the patient should receive his morphin in as small doses as will keep him comfortable up to the time of his evening or bedtime dose on this the second day, but he should receive no morphin or other opiate after taking the last purgative capsule of the second course. Again, six or eight hours after taking the last purgative capsule he should again receive his strychnin and his oil or saline, and this dose should be repeated until free bowel movement has been obtained. During this time the patient should be given a bath and put to bed. After this purgation and the elimination of the toxins that it causes he will be able to go much longer before he has the desire for the narcotic, especially if he remains in bed, which should be insisted on. In six or eight hours, however, after the usual time for his morning dose he will begin to require something for his relief. At this time instead of being given the opiate, he is given scopolamin in 1/200-grain doses, hypodermically, and the same dose is repeated in thirty minutes. Ordinarily a patient will go to sleep in half an hour after the second dose. If he does not, and still complains of discomforts, the third dose of the same size should be given. If he is not uncomfortable, however, he should not receive the third dose until an hour after the second dose. At the end of that time, however, he should receive a third dose. This dose, in patients who are not uncomfortable, may be of the same size or increased in size, depending on the amount of impression produced by the other doses. Of course, a patient may be susceptible to the action of scopolamin, or he may be tolerant to it, but if he is poisoned slightly by it (belladonna poisoning) he will not suffer from the need of his morphin.

The patient should be allowed to sleep from six to eight hours, unless he awakens before, but when he does awake, no matter how comfortable he may be, he should receive another dose of scopolamin, generally 1/200 grain. The amount is regulated by the susceptibility of the individual. This drug is then repeated at such intervals as are required to keep up a mild belladonna intoxication and keep the patient free from pain. He may sleep, or he may not.

This treatment with scopolamin should be continued for from thirty-six to forty-eight hours from the time of beginning the remedy and then stopped.

Pettey believes it generally advisable during the time of the administration of scopolamin to give 20 grains of sodium thiosulphate (sodium hyposulphite) every two hours for twenty-four hours or more (of course provided the patient is not comfortably sleeping), finding that this drug supplements the effect of the calomel purge and will cause bilious stools unattended by colic or griping.

At the end of the fifth or sixth day the patient is convalescent, and has no desire for the drug to which he is addicted, although, of course, he is weak and will miss the support of his usual stimulant. "The usual symptoms attendant on the withdrawal of morphin are not present, such as diarrheas, disturbed heart, nerve-pains, muscle-aches, nervousness and flushings, and the patient can lie comfortably in bed and take and enjoy his nourishment."

If the heart-action is deficient during this treatment, spartein sulphate in doses of 2 grains at intervals of from four to six hours is the medication Pettey advises.

The convalescence should be protracted; namely, from one to two months should be spent under the direct supervision of the physician, preferably in an institution accustomed to treat such patients. The after-treatment from the period just described on to complete health is the usual one for neurasthenics, namely, food, rest, physical treatments and more or less exercise.

Patients thus treated have a short convalescence, gain in weight, sleep well and are not injured by the ordeal of the withdrawal of the drug.

The convalescent patient should receive no drugs, unless there is some specific reason for administering them. Alcohol should be absolutely withheld. The same is true of strychnin. Alcohol is followed by depression, and its dulling effect on the nervous irritability is only short-lived. As previously stated, the nervous system is hyperesthetic after the withdrawal of the narcotic, and to stimulate it continuously with strychnin is a mistake.

If the heart-action becomes weak during the treatment, Pettey advises the use of spartein sulphate, 1 to 2 grains, hypodermically, every four to six hours. He finds that this drug acts better in sustaining the circulation after the withdrawal of morphin than any other drug.

Pettey discusses the large doses of strychnin which he advises, and finds that the larger the daily dose of morphin the more strychnin will be required to wake up the inert nerve-centers and to cause satisfactory catharsis and nutritional activities, and he is sure that failure to use sufficiently large doses of strychnin has sometimes caused failure in complete evacuation of the intestines and complete elimination of toxins.

Pettey discusses the use of scopolamin, and even goes so far as to state "that its relationship to the treatment of morphinism is the same as the relationship of ether to surgery." In other words, it inhibits pain and suffering.

We have long maintained[2] that some member of the atropin series was always used in the successful treatment of morphinism. Which particular form of the atropin group is to be used has varied with the different specialists in this line, but undoubtedly scopolamin offers the desired antagonistic effect to the morphin; namely, it causes nervous stimulation through its atropin constituent while at the same time it causes mental quietude as other forms of the atropin group do not.

Pettey finds that pregnancy is no bar to his treatment for the morphin habit, although he would take a longer time in the preparation of the patient for the withdrawal of the drug. He finds that scopolamin will arrest uterine activity.

New and Nonofficial Remedies

The following additional articles have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Their acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on investigation made by or under the direction of the Council. Criticisms and corrections are asked for to aid in the revision of the matter before publication in the book "New and Nonofficial Remedies."

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that, so far as known, it complies with the rules adopted by the Council.

W. A. Puckner, Secretary.

DIGIPURATUM AMPULES.—This dosage form of an accepted proprietary article has been accepted.

Each ampule contains 1 Cc. of a digipuratum solution, faintly alkaline and isotonic with the body fluids, equivalent to .1 gram (1½ grains) digipuratum.

DIGIPURATUM SOLUTION FOR ORAL USE.—This dosage form of an accepted proprietary article has been accepted.

Vials containing 10 [illegible] on, each Cc. representing .1 gram (1½ [illegible] The solution for oral use must not be [illegible]

TETANUS ANTITOXIN (See N. N. R., 1913. p. 218).

H. M. Alexander and Co., Marietta, Pa.

Tetanus Antitoxin.—This product is concentrated and refined according to the method of Banzhaf. It is standardized under the method approved by the Hygienic Laboratory of the United States Public Health Service. *Marketed* in a syringe containing 1500 units—a single immunizing dose.

ACNE VACCINE (See N. N. R., 1913, p. 221).

Lederle Antitoxin Laboratories, New York City. (Schieffelin and Co., New York.)

Acne Vaccine.—This product is marketed in five syringes containing respectively 5 million, 10 million, 20 million, 40 million and 100 million killed acne bacteria. Also marketed in four packages of two vials, each containing 5 million, 10 million, 20 million and 40 million killed bacteria. Also marketed in 20 Cc. vials in four strengths, 1 Cc. containing respectively 5 million, 10 million, 20 million and 40 million acne bacilli.

BACILLUS BORDET-GENGOU VACCINE.

Lederle Antitoxin Laboratories, New York City. (Schieffelin and Co., New York.)

Pertussis Vaccine.—This product is marketed in four syringes containing respectively, 25 million, 50 million, 100 million and 200 million killed Bordet-Gengou bacilli. Also marketed in four packages of two vials, each containing 25 million, 50 million, 100 million and 200 million killed bacteria. Also marketed in 20 Cc. vials in four strengths, 1 Cc. containing respectively 25 million, 50 million, 100 million and 200 million pertussis bacteria.

MENINGOCOCCUS VACCINE (See N. N. R, 1913, p. 223).

Lederle Antitoxin Laboratories, New York City. Schieffelin and Co., New York.)

Meningococcus Vaccine.—This product is marketed in a package containing three syringes: syringe 1 containing 500 million killed meningococci, while syringes 2 and 3 contain each 1 billion killed meningococci. The contents of these syringes should be injected subcutaneously at intervals of ten days. Also marketed in a package containing three vials: vial 1 containing 500 million and vials 2 and 3 containing each 1 billion killed meningococci.

BACILLUS COLI VACCINE (See Jour. A. M. A., May 10. 1913, p. 1461).

Lederle Antitoxin Laboratories, New York City. (Schieffelin and Co., New York.)

Coli Vaccine (Polyvalent).—Marketed in 20 Cc. vials in four strengths, 1 Cc. containing respectively 50 million, 100 million, 200 million and 400 million killed bacilli.

GONOCOCCUS VACCINE (See Jour. A. M. A., May 10, 1913, p. 1461).

Lederle Antitoxin Laboratories, New York City. (Schieffelin and Co., New York.)

Gonococcus Vaccine (Polyvalent).—Marketed in 20 Cc. vials in four strengths, 1 Cc. containing respectively 50 million, 100 million, 200 million and 400 million killed gonococci.

PNEUMOCOCCUS VACCINE (See Jour. A. M. A., May 10, 1913, p. 1461).

Lederle Antitoxin Laboratories, New York City. (Schieffelin and Co., New York.)

Pneumococcus Vaccine (Polyvalent).—Marketed in 20 Cc. vials in four strengths, 1 Cc. containing respectively 50 million, 100 million, 200 million and 400 million killed pneumococci.

STAPHYLOCOCCUS VACCINES (See Jour. A. M. A., May 10, 1913, p. 1461.

Lederle Antitoxin Laboratories, New York City. (Schieffelin and Co., New York.)

Staphylococcus Vaccine (Polyvalent).—Marketed in 20 Cc. vials in four strengths, 1 Cc. containing respectively 250 million, 500 million, 1 billion and 2 billion killed staphylococci.

Staphylococcus Albus Vaccine (Polyvalent).—Marketed in 20 Cc. vials in four strengths, 1 Cc. containing respectively 250 million, 500 million, 1 billion and 2 billion killed staphylococcus albus.

Staphylococcus Aureus Vaccine (Polyvalent).—Marketed in 20 Cc. vials in four strengths, 1 Cc. containing respectively 250 million, 500 million, 1 billion and 2 billion killed staphylococcus aureus.

STREPTOCOCCUS VACCINE (See Jour. A. M. A., May 17, 1913, p. 1541).

Lederle Antitoxin Laboratories, New York City. (Schieffelin and Co., New York.)

Streptococcus Vaccine (Polyvalent).—Marketed in 20 Cc. vials in four strengths, 1 Cc. containing respectively 50 million, 100 million, 200 million and 400 million streptococci.

TYPHOID VACCINE (See Jour. A. M. A., May 17, 1913, p. 1541).

Lederle Antitoxin Laboratories, New York City. (Schieffelin and Co., New York.)

Typhoid Vaccine.—Marketed in 20 Cc. vials in four strengths, 1 Cc. containing respectively 100 million, 250 million, 500 million and 1 billion killed typhoid bacilli.

MEDICAL COLLEGES OF THE UNITED STATES

ANNUAL PRESENTATION OF EDUCATIONAL DATA BY THE COUNCIL ON MEDICAL EDUCATION

Below are given brief descriptions of the medical colleges in the United States and Canada that are legally chartered to teach medicine, several of which do not grant degrees. The name, address, year of organization, history and date when first class graduated are given in each instance. Unless otherwise stated, a class graduated each subsequent year. Where official reports have been received from the college, information regarding faculty, entrance requirements, length of term, fees, students (excluding specials and postgraduates) graduates, name of dean and next session is given without discrimination, regardless as to whether the college is sectarian or not. In a few instances in which such reports were not received the information published is from other reliable sources. Figures for graduates include all who graduated since July 31, 1912. Extracts of rules and the membership of the Association of American Medical Colleges are shown following the list of colleges. Figures showing population of cities and states are taken from the United States Census Bureau's returns for 1910.

ALABAMA

Alabama, population 2,138,093, has two medical colleges, the Medical Department of the University of Alabama and the Birmingham Medical College, located, respectively, in Mobile and Birmingham. The population of Mobile is 51,521 and of Birmingham 132,685.

Birmingham

BIRMINGHAM MEDICAL COLLEGE, Avenue F and Twentieth Street. —*Chartered in 1894.* The first class graduated in 1895. In 1913 became the Graduate School of Medicine of the University of Alabama. There are 25 professors and 15 assistants, total 40. The course of undergraduate instruction now embraces two sessions of eight months each. Only juniors and seniors will be enrolled. When then two classes have graduated, the college will cease to do undergraduate teaching. The fees are $105 for the third year and $130 for the fourth. The Secretary is Dr. E. P. Hogan. Registration, 1912-1913, 102; graduates, 28. The twentieth session *begins Oct. 1, 1913, and ends May 21, 1914.*

Mobile

UNIVERSITY OF ALABAMA SCHOOL OF MEDICINE, St. Anthony and Lawrence Streets.—Organized in 1859 as the Medical College of Alabama. Classes were graduated in 1861 and in all subsequent years except 1862 to 1868, inclusive. It was reorganized as the Medical Department of the University of Alabama in 1897. The 92d session begins Sept. 24, 1913, and ends June 10, 1914.

Georgetown University School of Medicine,, 920 H Street, N.-W.—Organized in 1851. The first class graduated in 1852. The faculty contains 24 professors, 30 instructors and assistants; total 54. Two years of collegiate work are required for entrance. The course of study covers four terms of eight and one-half months each. The fees for the first year are $165, and for each of the other three years, $150. The Dean is Dr. George M. Kober. The registration for 1912-13 was 126; graduates 29. The 63d session begins Sept. 27, 1913, and ends June 13, 1914.

Howard University School of Medicine, Fifth and W Streets, N.-W.—Chartered in 1867. Organized in 1869. The first class graduated in 1871. Colored students compose a majority of those in attendance. The faculty comprises 19 professors and 22 lecturers and assistants, 41 in all. The admission requirements are one year of collegiate work including physics, chemistry, botany and zoology and a reading knowledge of one modern language besides English. The course covers four years of thirty weeks each. The fees of each of the four sessions respectively are $107, $102, $102 and $109. The Dean is Dr. Edward A. Balloch. Registration for 1912-13 was 122; graduates, 21. The 46th session begins Oct. 1, 1913, and ends June 3, 1914.

GEORGIA

Georgia, population 2,609,121, has four medical colleges; Medical College of Georgia, located in Augusta, population 41,040; Atlanta Medical College, the Georgia College of Eclectic Medicine and Surgery, and the Southern College of Medicine and Surgery are in Atlanta, a city of 154,839 population.

Atlanta

Atlanta Medical College.—Butler and Armstrong Streets.—Organized in 1854. Classes graduated, 1855 to 1861, when it suspended. Reorganized in 1865. In 1898 it merged with the Southern Medical College (organized in 1878) taking the name of Atlanta College of Physicians and Surgeons. In 1913 it merged with the Atlanta School of Medicine (organized in 1905), reassuming its first title. It has a faculty of 34 professors and 70 instructors, assistants, etc., a total of 104. The course of study is four years of thirty-two weeks each. The fees are $150 each year. The dean is Dr. W. S. Elkin. Total registration for the two colleges for 1912-13 was 560; graduates, 121. The next session begins Sept. 29, 1913, and ends June 1, 1914.

Georgia College of Eclectic Medicine and Surgery, Tanner Street, near Edgewood Avenue.—Organized in 1877 as the Georgia Eclectic Medical College. In 1884 it acquired the charter of the College of American Medicine and Surgery. It assumed its present name in 1886. The first class graduated in 1878. The faculty consists of 13 professors and 6 assistants, a total of 19. Tuition is $80 per year; graduation fee, $25. The Proctor is Dr. E. B. Thomas. Total registration for 1912-13 was 70; graduates, 42. The next session begins Sept. 20, 1913, and ends April 13, 1914.

Southern College of Medecine and Surgery, McDaniel Street. —Organized in 1911. The faculty numbers 13. Total registration for 1912-13, 53; graduates, 15. The Dean is Dr. W. B. Lingo.

Augusta

University of Georgia, College of Medicine, Railroad Avenue and Harper Street.—Organized in 1828 as the Medical Academy of Georgia, the name being changed to the Medical College of Georgia in 1829. Since 1873 it has been known as the Medical Department of the University of Georgia. Entire property transferred to the University in 1911. Classes were graduated in 1833 and in all subsequent years except 1862 and 1863. The faculty includes 23 professors and 28 assistants, 51 in all. Entrance requirements beginning Jan. 1, 1914, will be two years of collegiate work. The course is four years of eight months each. Fees for each of the four years respectively are $140, $135, $125 and $150. The Dean is Dr. W. H. Doughty, Jr. The total registration for 1912-13 was 80; graduates, 27. The 20th session begins Sept. 17, 1913, and ends May 27, 1914.

ILLINOIS

Illinois, population 5,638,591, has seven medical colleges, one of which gives instruction at night, all located in Chicago, a city of 2,185,283 inhabitants, and are as follows: Rush Medical College, Northwestern University Medical School, University of Illinois College of Medicine, Hahnemann Medical College, Bennett Medical College, Jenner Medical College and Chicago College of Medicine and Surgery.

Chicago

Rush Medical College.—This school was founded in 1837, organized in 1843, was the medical department of Lake Forest University from 1887 until 1898, when it became affiliated with the University of Chicago. The first class graduated in 1844. The faculty is composed of 103 professors, 151 associates, instructors etc., a total of 254. The requirements for admission are two years of college work, including courses in college chemistry, physics and biology, and a reading knowledge of German or French. The course covers four years of eight and a half months each. A fifth year, consisting of a hospital internship or of a fellowship in one of the departments, will be required of all students matriculating for the summer quarter of 1914 and thereafter. All freshmen and sophomore studies are given at the University of Chicago. The last two years are given in the clinical building at the corner of Wood and Harrison Streets. The total fees are $180 each year. A matriculation fee of $5 is paid but once, and there are incidentals amounting from $2 to $5 annually. The Dean is Dr. John M. Dodson. Total registration 1912-13 was 422; graduates, 95. The 71st session begins Oct. 1, 1913, and ends June 10, 1914.

Northwestern University Medical School, South Dearborn Street, between Twenty-fourth and Twenty-Fifth Streets.—Organized in 1859 as the Medical Department of Lind University. In 1864 it became independent as the Chicago Medical College. It united with Northwestern University in 1869, but retained the name of Chicago Medical College until 1891, when the present name was taken. The faculty comprises 55 professors and 83 lecturers and assistants, a total of 138. The requirements for admission are such as will admit to the College of Liberal Arts of Northwestern University plus two years of college work including courses in physics, chemistry, biology and modern languages. The course covers four years of eight months each. The fees for the four years respectively are $200, $200, $191 and $185. The Dean is Dr. Arthur R. Edwards. The total registration for 1912-13 was 196; graduates, 56. The 54th session begins Sept. 30, 1913, and ends June 6, 1914.

University of Illinois College of Medicine, Honore and Congress Streets.—Organized in 1882 as the College of Physicians and Surgeons. The first class graduated in 1883. It became the Medical Department of the University of Illinois by affiliation in 1896 and an integral part in 1910. The relationship with the university was canceled in June, 1912, but restored in March, 1913. The American Medical Missionary College was absorbed in 1910. The faculty is composed of 40 professors, 93 assistants and instructors, a total of 133. The fees are $155 each year. The Dean is Dr.

William E. Quine. Total registration for 1912-13 was 535; graduates, 133. The 32d session begins Oct. 1, 1913, and ends June 9, 1914.

Chicago College of Medicine and Surgery, 706 South Lincoln Street.—Organized in 1901 as the American College of Medicine and Surgery (Chicago Eclectic Medical College). The latter part of the name was dropped in 1902 and it became the Medical Department of Valparaiso University. Eclecticism was dropped in 1905. The name was changed to the above in 1907. The course covers four years of eight months each. The faculty numbers 138. The total fees of each of the four years are $100. The Registrar is Dr. G. E. Wyneken. The total registration for 1912-13 was 642; graduates 188. The 13th session begins Sept. 30, 1913, and ends May 25, 1914.

Hahnemann Medical College and Hospital of Chicago, 2811 Cottage Grove Avenue.—Organized in 1859. The first class was graduated in 1861. The faculty includes 29 professors and 41 lecturers, assistants, etc., a total of 70. The course extends over four years of eight months each. The tuition fees for the four years respectively are $125, $125, $155 and $175. The Registrar is Dr. W. Henry Wilson. The total registration for 1912-13 was 76; graduates 31. The 54th session begins Sept 29, 1913, and ends May 28, 1914.

Bennett Medical College, Fulton and Ada Streets.—Organized in 1868 as the Bennett College of Eclectic Medicine and Surgery. Dropped Eclecticism in 1909. In 1910 it united with the Illinois Medical College and became by affiliation the Medical Department of Loyola University. The first class graduated in 1870. The faculty numbers 86. The course covers four years of thirty-four weeks each. The fees for the four years respectively are $150, $150, $125 and $175. The Dean is Dr. Maximillian Herzog. The total registration for the two colleges in 1912-13 was 395; graduates, 43. The next session begins Oct. 1, 1913, and ends June 20 1914.

Jenner Medical College, an afternoon and night school, located at 223 West Washington Street.—Organized in 1892. Classes were graduated in 1896 and in all subsequent years. The faculty numbers 48. The Secretary is Dr. John D. MacKellar. Total registration for 1912-13, 191; graduates, 11. The next session begins Sept. 2, 1913, and ends June 13, 1914. *Official statements received indicate that diplomas from this college are not recognized by the licensing boards of twenty-nine states.*

INDIANA

Indiana, population 2,700,876, has one medical college, the Indiana University School of Medicine, located at Indianapolis, a city of 233,650 people, except that the work of the first year is offered also at Bloomington, the seat of the University.

Bloomington and Indianapolis

Indiana University School of Medicine.—Organized in 1893, medical course until 1905. In 1907, by union with the State College of Physicians and Surgeons, the complete course in medicine was offered. In 1908 the Indiana Medical College, which was formed in 1907 by the merger of the Medical College of Indiana (organized in 1869) and the Fort Wayne College of Medicine (organized in 1879) merged into it. The faculty consists of 76 professors and 47 lecturers, associates and assistants, a total of 123. Two years of collegiate work are required for admission The work of the first year is emphasize [illegible] The work of the other three years is all [illegible]es for the four years respectively are $100. [illegible] fifth optional year leading to the "M.D. [illegible] added. The Secretary at Bloomington is Dr. B. D. Myers; the Dean is Dr. Charles P. Emerson, Indianapolis. The total registration for 1912-13 was 146; graduates 47. The next session begins Sept. 25, 1913, and ends June 24, 1914.

IOWA

Iowa, population 2,224,771, has two medical colleges. The College of Medicine and the College of Homeopathic Medicine of the State University of Iowa, both located in Iowa City, population 10,091.

Iowa City

State University of Iowa College of Medicine. University Campus.—Organized in 1869. First session began in 1870. First class graduated in 1871. The faculty is made up of 20 professors, 21 lecturers, demonstrators and assistants, a total of 41. Two years of collegiate work, including courses in physics, chemistry, biology and French or German, are required for admission. The course of study covers four years of thirty-six weeks each. Total fees for each year are $50 plus a matriculation fee of $10 paid but once and a graduation fee of $10. The Dean is Dr. James R. Guthrie, Dubuque. Total registration for 1912-13 was 99; graduates, 16. The 44th session begins Sept. 22, 1913, and ends June 17 1914.

State University of Iowa College of Homeopathic Medicine.—Organized in 1877. The first class graduated in 1878. The faculty is composed of 11 professors and 19 lecturers and assistants, a total of 30. The work of the first two years is taken in classes with the students of the College of Medicine of the State University of Iowa, and it has the same entrance requirements. The fees are $50 each year, plus a matriculation fee of $10, paid but once, and a graduation fee of $10. The Dean is Dr. George Royal. Total registration for 1912-13 was 13; graduates, 6. The 36th session begins Sept. 22, 1913, and ends June 17 1914.

KANSAS

Population 1,690,949, has one medical college. The School of Medicine of the University of Kansas gives its first two years in Lawrence, population 12,915, and the last two years in Rosedale, a suburb of the Two Kansas Cities, which together have a population of 330,662.

Lawrence and Rosedale

University of Kansas School of Medicine.—Organized in 1880. In 1905 it merged with the Kansas City (Mo.) Medical College, founded in 1869, the College of Physicians and Surgeons, founded in 1894, and the Medico-Chirurgical College, founded in 1897. Absorbed Kansas Medical College in 1913. The faculty, including lecturers and clinical assistants, numbers 56. The requirements for admission are two years of collegiate work. The course covers four years of nine months each. The total fees are, for each of the first two years, $30 per year (and for non-residents of the state, $45); for the last two years $100 and $110, respectively. The Dean is Dr. S. J. Crumbine, Topeka; Associate Dean, Dr. M. T. Sudler. The total registration for 1912-13 was 66; graduates, 7. The 34th session begins Sept. 17, 1913, and ends June 10, 1914.

KENTUCKY

Kentucky, population 2,289,905, has one medical college, the University of Louisville Medical Department, situated in Louisville, a city of 223,928 inhabitants.

Louisville

University of Louisville Medical Department, First and Chestnut Streets.—Organized in 1837 as the Louisville Medical Institute. The first class graduated in 1838, and a class graduated in each subsequent year except 1863. In 1846 the present name was assumed. In 1907 it absorbed the Kentucky University Medical Department. In 1908 it absorbed the Louisville Medical College, the hospital College of Medicine and the Kentucky School of Medicine. It has a faculty of 35 professors and 38 lecturers and assistants, a total of 73. After Jan. 1, 1914, two years of collegiate work will be required for admission. The course covers four years of thirty-two weeks each. The fees are $150 for each of the first three years and $160 for the fourth; graduation fee, $25. The Dean is Dr. W. Edward Grant. The total registration for 1912-13 was 255; graduates, 77. The next session begins Oct. 1, 1913, and ends May 29, 1914.

LOUISIANA

Louisiana, having a population of 1,656,388, contains one medical college, the School of Medicine of the Tulane University of Louisiana, situated in New Orleans, a city of 339,075.

New Orleans

School of Medicine of the Tulane University of Louisiana, University Campus and 1551 Canal Street.—Organized in 1834 as the *Medical College of Louisiana.* Classes were graduated in 1835 and in all subsequent years, except 1863-65, inclusive. It was *transferred to Medical Department* of the University of Louisiana in 1847 *and became the* Medical Department of the Tulane University in 1884. The faculty has 21 professors and 96 instructors, *demonstrators, etc., a total of 117.* The course covers four years *of thirty-two weeks each.* One year of collegiate work is required for admission. Total fees are $180 per year; graduation fee, $30. *The Dean is Dr. Isadore Dyer.* The total registration for 1912-13 was 296; *graduates, 79.* The 80th session begins Sept. 29, 1913, and ends June 3, 1914.

MAINE

Maine, population 742,371, has one medical college, located *in Brunswick and Portland,* the latter having a population of 58,571.

Brunswick-Portland

Medical School of Maine. The medical department of Bowdoin College. The first two years are given at Bowdoin College, Brunswick, the last two at Portland, building located on Chadwick Street.—Organized in 1820. The first class graduated in 1820. The faculty numbers 63. The course covers four years of eight months each. The total fees are $120 for the first year and $110 for each of the other three years. *The Dean is Dr. Addison S.* Thayer, 10 Deering Street, Portland. The total number of students in 1912-13 was 75; *graduates,* 13. The 93d session begins Oct. 16, 1913, and ends June 24, 1914.

MARYLAND

Maryland, with a population of 1,295,346, contains three medical colleges, all located in Baltimore, a city with 558,485 inhabitants. They are as follows: Johns Hopkins University Medical Department, School of Medicine of the University of Maryland and the College of Physicians and Surgeons.

Baltimore

Johns Hopkins University Medical Department, Washington and Monument Streets.—Organized *in 1893.* The first class graduated in 1897. The faculty consists of 39 professors and 79 clinical professors, etc., a total of 118. The requirements for admission demand that the applicant either has (a) completed the chemical-biologic course which leads to the A.B. *degree* in the university or (*b*) graduated at an approved college or scientific school and has a knowledge of French and German, *physics,* chemistry and biology, such as may be obtained from a *year's course.* The course extends over four years of eight and one-half months each. The charge for tuition is $200 per annum. *The Dean* is Dr. J. Whitridge Williams. Total registration for 1912-13 was 351; graduates, 76. The 21st session begins Oct. 1, 1913, and ends June 10, 1914.

College of Physicians and Surgeons, Calvert and Saratoga Streets.—Organized in 1872. The first class graduated in 1873.

In 1878 it united with Washington University School of Medicine. The faculty consists of 17 professors and 52 lecturers, demonstrators, etc., a total of 69. The work covers four years of eight months each. Total fees are $165 each year; graduation fee $30. The Dean is Dr. William F. Lockwood. The total number of students registered in 1912-13 was 234; graduates, 60. The 42d session begins Oct. 1, 1913, and ends June 4, 1914.

University of Maryland School of Medicine, Lombard and Greene Streets.—Organized in 1807 as the College of Medicine of Maryland. The first class graduated in 1810. In 1812 it became the University of Maryland School of Medicine. Baltimore Medical College was merged into it in 1913. The faculty numbers 135. The course covers four years of eight months each.. The total fees are $170 each year; graduation fee, $30. The Dean is Dr. R. Dorsey Coale. The total number of students registered in 1912-13 was 293; graduates, 49. The 107th session begins Oct. 1, 1913, and ends June 1, 1914.

MASSACHUSETTS

Massachusetts, population 3,366,416, has four medical colleges: Medical School of Harvard University, Boston University School of Medicine, College of Physicians and Surgeons and Tufts College Medical School. They are all situated in Boston, a city of 670,585.

Boston

Medical School of Harvard University, Longwood Ave.—Organized in 1782. The first class graduated in 1788. It has a faculty of 53 professors and 141 associates, assistants, etc., a total of 194. Candidates for admission must present credits for two years of work in a recognized college or scientific school, which must include courses in physics, chemistry, biology and French or German. The session is four years of nine months each. The total fees for each of the first two years respectively are $234 and $208; for each of the last two years, $200. The Dean is Dr. Edward H. Bradford. The total registration for 1912-13 was 285; graduates, 60. The 132d session begins Sept. 22, 1913, and ends June 18, 1914.

Boston University School of Medicine, 80 East Concord Street.—Organized in 1873. In 1874 the New England Female Medical College, founded in 1848, was merged into it. The first class graduated in 1874. The faculty includes 32 professors, 38 associates, etc., a total of 70. The course covers four years of eight months each. Total fees for the first, second and third years, $125 each, and for the last year $155. The Dean is Dr. John P. Sutherland. Total registration for 1912-13 was 98; graduates, 11. The 41st session begins Oct. 2, 1913, and ends June 3, 1914.

Tufts College Medical School, 416 Huntington Avenue.—Organized in 1893 as the Medical Department of Tufts College. The first class graduated in 1894. It has a faculty of 34 professors and 77 assistants, lecturers, etc., a total of 111. The course covers four years of eight months each. The total fees are $155 each year. The Secretary is Dr. Frederic M. Briggs. Total registration for 1912-13 was 317; graduates, 85. The 20th session begins Sept. 24, 1913, and ends June 1, 1914.

College of Physicians and Surgeons, 517 Shawmut Avenue.—Organized in 1880. The first class graduated in 1882. The college announcement gives the names of 180 "matriculants and applicants" for the session of 1912-13, which included both dental and medical students. The names of some of the students who graduated in 1910 appear in the announcements of this school from six to nine years. The Dean is Dr. Thomas D. Crothers. Total registration for 1912-13 was about 80; graduates, 19. *This college has been reported not recognized by the Massachusetts Medical Society.*

MICHIGAN

Michigan, population 2,810,173, has three medical colleges. Two of these, the University of Michigan Department of Medicine and Surgery and the Homeopathic College of the University of Michigan, are located at Ann Arbor, a city of 14,817 people. The Detroit College of Medicine is located at Detroit, a city of 465,766 inhabitants.

Ann Arbor

University of Michigan Department of Medicine and Surgery.—Organized in 1850. The first class graduated in 1851. It has a faculty composed of 18 professors and 66 associates, instructors, etc., a total of 84. The entrance requirements are two years of college work, including courses in chemistry, physics and biology, with laboratory work, and a reading knowledge of one modern language. The curriculum embraces four years of nine months each. The total fees for Michigan students for the entire course of four years is $350 and for others about $400. The Dean is Dr. Victor C. Vaughan. The total registration for 1912-13 was 221; graduates, 42. The sixty-fourth session begins Sept 30, 1913, and ends June 25, 1914.

University of Michigan Homeopathic College.—Organized in 1875. The first class graduated in 1877. Although the work of the first two years is taken in the same classes with the Department of Medicine and Surgery of the University of Michigan, nevertheless the entrance requirements have been kept at one year of collegiate work and even then with an allowance of conditions in as much as eight hours, the requirements for the other departments are two years of collegiate work. The Dean is Dr. W. B. Hinsdale. The total registration for 1912-13 was 63; graduates, 13. The next session begins Sept. 30. 1913, and ends June 25, 1914.

Detroit

Detroit College of Medicine, St. Antoine, Catherine and Mullett Streets and Gratiot Avenue.—Organized in 1885 by consolidation of Detroit Medical College, organized in 1868, and the Michigan College of Medicine, organized in 1880. The first class graduated in 1886. The faculty embraces 23 professors, 102 lecturers, instructors, etc., a total of 125. The course covers four years of eight months each. The Registrar is Dr. F. B. Walker. The total registration for 1912-13 was 197; graduates, 27. The twenty-ninth session begins Sept. 7, 1913, and ends June 4, 1914.

MINNESOTA

Minnesota, population 2,075,708, contains one medical school, the University of Minnesota Medical School, situated in Minneapolis. Minneapolis and St. Paul are practically one city, and have a combined population of 516,162.

Minneapolis

University of Minnesota Medical School.—Organized in 1883; reorganized in 1888 by absorption of St. Paul Medical College and Minnesota Hospital Medical College. The first class graduated in 1889. In 1908 the Minneapolis College of Physicians and Surgeons, organized in 1883, was merged. In 1909 the Homeopathic College of Medicine and Surgery was merged. The faculty includes 10 professors and clinical professors and 76 associate professors, assistants, etc., a total of 86. The curriculum covers four years of nine months each and a year's internship in an approved hospital. The entrance requirements are two years of university work which must include one year each of physics, general chemistry, qualitative analysis, zoology or botany, and French or German, all in addition to a four-year high-school course, including two years of Latin. Students entering hereafter will be required to secure a degree of B.S. or A.B. before the M.D. is granted. Total fees are $150 each year. The Dean is Dr. E. P. Lyon. The total registration for 1912-13 was 176; graduates, 45. The twenty-sixth session begins Sept. 17, 1913, and ends June 11, 1914.

MISSISSIPPI

Mississippi, population 1,797,114, has one medical college, the Medical Department of the University of Mississippi, which is located at Oxford, a city of 1,825 inhabitants.

Oxford

University of Mississippi Medical Department.—Organized in 1903. Gives only the first two years of the medical course. The session extends over eight and a half months. The total fees each year are respectively $102 and $100. The faculty numbers 13. The Dean is Dr. W. S. Leathers. The total registration for 1912-13 was 38. The eleventh session begins Sept. 18, 1913, and ends June 2, 1914.

MISSOURI

Missouri, population 3,293,335, has eight medical colleges. St. Louis, population 687,029, contains five of these, viz., the School of Medicine of St. Louis University, Washington University Medical Department, St. Louis College of Physicians and Surgeons and the American Medical College. Kansas City, which with Kansas City, Kan., has a total population of 330,662, has two colleges, namely: the Kansas City Hahnemann Medical College and the Eclectic Medical University. Ensworth Medical College is located in St. Joseph, population 77,403. The Department of Medicine of the University of Missouri is at Columbia, a town of 9,662 people.

Columbia

University of Missouri School of Medicine.—Organized at St. Louis in 1845; was discontinued in 1859, but was reorganized at Columbia in 1872. Teaching of the clinical years was suspended in 1909. The faculty includes 9 professors and 6 assistant professors, lecturers, etc., a total of 15. The course covers two years of nine months each. The entrance requirements are two years of college work including English, 5 hours; German, 5 hours; general zoology, 5 hours; physics, 5 hours; inorganic chemistry, 5 hours; elective, 35 hours. Equivalent work in foreign language may be substituted for the English and German. Total fees are $60 each year. Total registration of students for 1912-13 was 45. The next session begins Sept. 18, 1913, and ends June 4, 1914.

Kansas City

Kansas City Hahnemann Medical College, 916 Tracy Avenue.—Organized in 1888 as the *Kansas City Homeopathic Medical College.* The first class graduated in 1899. In 1902 it united with the Hahnemann Medical College of the Kansas City University, taking the present title. The Dean is Dr. Moses T. Runnels. Total registration for 1912-13 was 55; graduates, 8. The next session begins Sept. 18, 1913, and ends May 21, 1914.

Eclectic Medical University, 1423 Independence Avenue.—Organized at Kansas City, Mo., in 1898 with the present title. Moved to Kansas City, Kan., in 1907, and took the name of Western Eclectic College of Medicine and Surgery. Returned to Kansas City, Mo., in 1909 and resumed the present title. First class graduated in 1900. Fees are $100 each year. The Secretary is Dr. D. R. Alexander. The total registration for 1912-13 was 50; graduates, 13. *Reported not in good standing by the Missouri State Board of Health and by twenty other state licensing boards.*

St. Joseph

The Ensworth Medical College, Seventh and Jule Streets.—Organized in 1876 as the St. Joseph Hospital Medical College. In 1882 it merged with the College of Physicians and Surgeons to form the St. Joseph Medical College. In 1888 changed name to Ensworth Medical College. In 1905 merged with the Central Medical College, organized in 1894, to form the Ensworth-Central

Medical College. In 1907 the present title was resumed. Will close in 1914. The faculty numbers 34. Only seniors will be registered. Fees, $125. The Secretary is Dr. T. E. Potter. Total registration for 1912-13 was 20; graduates, 7. The next session begins Sept. 20, 1913, and ends about May 20, 1914.

St. Louis

Washington University Medical School, 1806 Locust Street. Organized in 1842 as the Medical Department of St. Louis University. In 1855 it was chartered as an independent institution under the name of St. Louis Medical College. The first class graduated in 1843. In 1891 it became the Washington University Medical School. In 1899 it absorbed the Missouri Medical College. The faculty comprises 23 professors and 51 lecturers, instructors, etc., a total of 74. Two full years of college work are required for admission including courses in English, physics, chemistry and biology and a reading knowledge of German. The course is four years of eight months each. The total fees for the four years are, respectively, $155, $150, $150 and $155. The Dean is Dr. Eugene L. Opie. The total registration for 1912-13 was 66; graduates, 28. The next session begins Sept. 25, 1913, and ends June 11, 1914.

St. Louis University School of Medicine, 1402 South Grand Avenue.—Organized in 1901 by union of Marion-Sims Medical College, organized in 1890, and Beaumont Hospital Medical College, organized in 1886. It became the Medical Department of St. Louis University in 1903. The faculty is composed of 43 professors, 67 lecturers and assistants, a total of 110. One year of college subjects preliminary to the four years of medical subjects is given in the medical school. The curriculum covers four years of thirty-four weeks each. The total fees are $130 each year. The total registration for 1912-13 was 233; graduates, 69. The next session begins Oct. 1, 1913, and ends June 7, 1914.

St. Louis College of Physicians and Surgeons, Jefferson Avenue and Gamble Street.—Organized in 1869. Classes graduated in 1870 and each subsequent year until 1873, when it suspended. It was reorganized in 1879. Classes graduated in 1880 and subsequent years. The fees for the four years are, respectively, $110, $105, $100 and $95. The Secretary is Dr. E. T. Brand. Total registration for 1912-13 was 38; graduates, 10. The next session begins Sept. 15, 1913, and ends May 17, 1914.

American Medical College, 407 South Jefferson Avenue.—Organized in 1873 as an Eclectic College. Eclecticism dropped in 1910. Absorbed the Barnes Medical College in 1911. Became the Medical Department of the National University of Arts and Sciences in 1912. Two classes were graduated each year from 1874 to 1883, inclusive. Since then one class has graduated each year. The course covers four years of eight and a half months each. Fees: matriculation, $5; tuition each year, $135. The Dean is Dr. James Moores Ball. The total registration for 1912-13 was 211; graduates, 33. The next session begins Sept. 23, 1913, and ends June 6, 1914.

NEBRASKA

Nebraska, population 1,192,214, has three medical colleges. The University of Nebraska College of Medicine and the John A. Creighton Medical College of Omaha, population 124,096, and the Cotner Medical College at Lincoln, population 43,973.

Bethany-Lincoln

Cotner Medical College. Eclectic. University Campus, Bethany, and corner 13th and P Streets, Lincoln. It is the Medical Department of Cotner University.—Organized in 1890 as the Lincoln Medical College. Assumed present title in 1911. The first class graduated in 1891. The Registrar is Prof. R. L. Hoff, Bethany. The total registration for 1912-13 was 35; graduates, 7. The next session begins Sept. 15, 1913, and ends May 28, 1914.

Omaha

John A. Creighton Medical College, Fourteenth and Davenport Streets. It is the Medical Department of Creighton University.—Organized in 1892. The first class graduated in 1895. It has a faculty of 18 professors and 30 associates, lecturers and assistants, a total of 48. The course of study embraces four years of eight months each. The total fees for the four years, respectively, are $140, $130, $130 and $130. The Dean is Dr. A. L. Muirhead. Total registration for 1912-13 was 182; graduates, 39. The twenty-second session begins Sept. 1, 1913, and ends April 30, 1914.

College of Medicine University of Nebraska, Forty-second Street and Dewey Avenue.—Organized in 1881 as the Omaha Medical College. The first class graduated in 1882. It became the Medical Department of Omaha University in 1891. In 1902 it affiliated with the University of Nebraska, with the present title. The first two years were given at Lincoln and the last two in Omaha until 1913 when all four years were transferred to Omaha. The faculty is composed of 31 professors and 27 lecturers and instructors, total 58. Two years of collegiate work are required for admission including courses in physics, chemistry, zoology and German. The fees are approximately $100 per annum. The Acting-Dean is Dr. Robert H. Wolcott. Total registration for 1912-13 was 78; graduates, 9. The next session begins Sept. 9, 1913, and ends May 29, 1914.

NEW HAMPSHIRE

New Hampshire, population 443,140, has one medical college, located at Hanover, population 1,884.

Hanover

Dartmouth Medical School.—Organized as New Hampshire Medical Institute in 1797. The first class graduated in 1798. It is the Medical Department of Dartmouth College. The faculty is made up of 25 professors and 3 instructors, a total of 28. Two years of collegiate work are required for admission. The course covers four years of eight months each. After the class of 1914 has graduated the school will discontinue clinical teaching. The fees for the four years are, respectively, $160, $162, $125 and $125. The Dean is Dr. John M. Gile. The total registration for 1912-13 was 27; graduates, 10. The work of the first and second years begins with that of the academic department Sept. 19, 1913, and ends June 21, 1914; for the advanced classes the course begins Aug. 5, 1913, and ends April 24, 1914.

NEW YORK

New York State, population 9,113,614, has ten medical colleges. Seven of these, College of Physicians and Surgeons (Columbia University), Long Island College Hospital, New York Homeopathic Medical College and Hospital, New York Medical College and Hospital for Women, Cornell University Medical College, the University and Bellevue Hospital Medical College and Fordham University School of Medicine, are located in New York City, population 4,766,883. Albany Medical College is located in Albany, a city of 100,253 people. The University of Buffalo Medical Department is situated in Buffalo, population 423,715. The College of Medicine, Syracuse University, is in Syracuse, a city of 137.249 inhabitants.

Albany

Albany Medical College, Lancaster and Jay Streets.—Organized in 1838. The first class graduated in 1839. It became the Medical Department of Union University in 1873. The faculty is composed of 28 professors and 75 lecturers, assistants, etc., a total of 103. The curriculum covers four years of eight months each. Fees: First year, $130; second year, $145; third year, $120, and fourth year, $130. The Registrar is Dr. Willis G. Tucker. The total registration for 1912-13 was 239; graduates, 48. The eighty-third session begins Sept. 23, 1913, and ends May 26, 1914.

Buffalo

University of Buffalo Medical Department, High Street, near Main.—Organized in 1846. The first class graduated in 1874. It absorbed the Medical Department of Niagara University in 1898. The faculty is composed of 34 professors and 56 lecturers, assistants, etc., a total of 90. The course covers four years of eight months each. The total fees for the four years, respectively, are $185, $180, $140 and $140. The Dean is Dr. Herbert U. Williams. Total registration for 1912-13 was 221; graduates, 43. The sixty-eighth session begins Sept. 22, 1913, and ends June 5, 1914.

New York

Columbia University College of Physicians and Surgeons, 437 West Fifty-Ninth Street.—Organized in 1807 by the regents of the University of the State of New York as their medical department. The first class graduated in 1811. Affiliated with Columbia College in 1814 and was permanently connected in 1860, when it became the Medical Department of Columbia College. That institution became Columbia University in 1891. The faculty is composed of 67 professors and 138 instructors, demonstrators, etc., a total of 205. Two years of collegiate work, including courses in physics, chemistry and biology, are required for admission. The work covers four years of eight months each. The Dean is Dr. Samuel W. Lambert. The total fees for the first year are $255; for the second and third, $250, and $275 for the fourth year. Total registration for 1912-13 was 339; graduates, 99. The 106th session begins Sept. 24, 1913, and ends June 3, 1914.

Cornell University Medical College, First Avenue and Twenty-Eighth Street, New York City, and Ithaca.—Organized in 1898. The first class was graduated in 1899. The work of the first year may be taken either in Ithaca or New York. The faculty is composed of 50 professors and 95 assistants, lecturers, instructors, etc., a total of 145. All candidates for admission must be graduates of approved colleges or scientific schools or seniors of approved colleges which will permit them to substitute the first year of this medical school for the fourth year of their college course and will confer on them the Bachelor degree on the completion of the year's work. The candidate must also have such knowledge of physics, inorganic chemistry and biology as may be obtained in college by a year's course in these subjects when accompanied by laboratory work. Fees: First and fourth years, $190 each; second and third, $185 each. The Dean is Dr. William M. Polk. Total registration for 1912-13 was 102; graduates, 19. The sixteenth session begins Oct. 1, 1913, and ends June 11, 1914

Fordham University School of Medicine, Third and Pelham Avenues.—Organized in 1905. First class graduated in 1909. The faculty consists of 49 professors and 44 lecturers and assistants, a total of 93. The course of instruction covers four years of eight and a half months each. Fees, $200 each year. A year's work in a recognized college of liberal arts is required for admission. The Dean is Dr. William P. Healy. The total registration for 1912-13 was 136; graduates, 31. The ninth session begins Sept. 26, 1913. and ends June 10, 1914.

Long Island College Hospital, Henry Street, near Atlantic Avenue, Brooklyn.—Organized in 1858. The first class graduated in 1860. It has a faculty of 37 professors and 44 assistants, instructors, etc., a total of 81. The course covers four years of eight months each. Fees: First year, $205; second year, $200; third, $180, and $200 for the fourth year. The Secretary is Dr. Joseph H. Raymond. Total registration 1912-13 was 438; graduates, 69. The fifty-sixth session begins Sept. 23, 1913, and ends June 1, 1914.

New York Homeopathic Medical College and Flower Hospital, Eastern Boulevard, between Sixty-Third and Sixty-Fourth Streets.—Organized in 1858. Incorporated in 1860 as the Homeopathic Medical College for the State of New York. The present title was assumed in 1869. The first class graduated in 1861. The faculty consists of 43 professors and 42 assistants, lecturers, etc., a total of 85. The Dean is Dr. Royal S. Copeland. Total registration for 1912-13 was 245; graduates, 45. The fifty-fourth session begins Oct. 1, 1913, and ends May 29, 1914.

New York Medical College and Hospital for Women, (Homeopathic) 17-19 West One Hundred and First Street.—Organized in 1863. The first class graduated in 1864. The faculty consists of 30 professors and 20 lecturers and assistants, a total of 50. The course covers four years of thirty weeks each. The fees for each of the four years, respectively, are $155, $150, $135 and $155. The Dean is Dr. Emily C. Charles. The total registration for 1912-13 was 45; graduates, 9. Matriculants are not listed in the annual announcement. The fifty-first session begins Sept. 30, 1913, and ends May 24, 1914.

University and Bellevue Hospital Medical College, First Avenue and Twenty-Sixth Street.—Organized in 1898 by the union of the New York University Medical College, organized in 1841, and the Bellevue Hospital Medical College, organized in 1861. It is the Medical Department of New York University. The faculty is composed of 44 professors and 135 instructors, etc., in all 179. The course covers four years of eight months each. The fees are $200 per year; graduation fee, $25. The Dean is Dr. Egbert Le Fevre. Total registration for 1912-13 was 352; graduates, 75. The next session begins Sept. 24, 1913, and ends June 10, 1914.

Syracuse

Syracuse University College of Medicine, 307-311 Orange Street.—Organized in 1872, when the Geneva Medical College was removed to Syracuse, under the title "The College of Physicians and Surgeons of Syracuse University." Present title assumed in 1875. The first class graduated in 1873 and a class graduated each subsequent year. In 1884 the amalgamation with the university was made complete. Two years of a recognized college course are required for admission. The course covers four years of thirty-two weeks each. The total fees for each of the four years are respectively, $186, $186, $146 and $161. The faculty is composed of 23 professors and 48 associate and assistant professors, lecturers and instructors. The Dean is Dr. John L. Heffron. The total enrollment for 1912-13 was 87; graduates, 21. The forty-second session begins Sept. 30, 1913, and ends June 10, 1914.

NORTH CAROLINA

North Carolina, population 2,206,287, has four medical schools, two of which give only the first two years of the medical course. The Medical Department of the University of North Carolina is located at Chapel Hill, population 1,200. The Leonard School of Medicine is at Raleigh, population 19,218. The North Carolina College is at Charlotte, population 34,014. Wake Forest School of Medicine is at Wake Forest, population 823.

Chapel Hill

University of North Carolina Medical Department.—Organized in 1890. Until 1902 this school gave only the work of the first two years, when the course was extended to four years by the establishment of a department at Raleigh. The first class graduated in 1903. A class was graduated each subsequent year, including 1910, when the clinical department at Raleigh was discontinued. The faculty is composed of 12 professors and 17 lecturers, assistants, etc., a total of 29. The total fees for the two years, respectively, are $115 and $116. The Dean is Dr. I. H. Manning. The total registration for 1912-13 was 54. The twenty-eighth session begins Sept. 8, 1913, and ends June 3, 1914.

Charlotte

North Carolina Medical College, Church and Sixth Streets.—Organized in 1887 at Davidson as the Davidson School of Medicine. It was a preparatory school only, not granting any degrees until 1903, when it was chartered under its present name. The first class was graduated in 1893. Removed to Charlotte in 1907. The faculty numbers 42. The course covers four years of eight months each. The fees for the four years are, respectively, $107, $102, $100 and $130. The Dean is Dr. Walter O. Nisbet. The total registration for 1912-13 was 85; graduates, 26. The next session begins Oct. 1, 1913, and ends June 1, 1914.

Raleigh

Leonard Medical School.—Colored. This department of Shaw University was established in 1882. Classes were graduated in 1886, 1888 and in all subsequent years. It has a faculty of 14. Bardeen. The registration for 1912-13 was 66. The sixth session begins Sept. 25, 1913, and ends June 17, 1914.

Milwaukee

Marquette University School of Medicine, Fourth Street and Reservoir Avenue.—Organized in December, 1912, by the merger of the Milwaukee Medical College and the Wisconsin College of Physicians and Surgeons. It has a faculty of 71 professors and 45 assistants, instructors, etc., a total of 116. Beginning this fall the entrance requirements include, in addition to a four-year high school education, one year of college work including courses in physics, chemistry, biology and a modern language. Beginning with the session of 1914-15, two years of college work will be required. The curriculum is for four years of thirty-four weeks each. The total fees for the four years, respectively, are $165, $160, $155 and $155. The Dean is Dr. Louis F. Jermain. The registration for 1912-13 was 283; graduates, 78. The second session begins Oct. 1, 1913, and ends June 18, 1914.

PHILIPPINE ISLANDS

The Philippine Archipelago, having a population of 7,635,436, has two medical colleges, the University of the Philippines College of Medicine and Surgery and the Medical Faculty of the University of St. Thomas. They are located in the city of Manila, which in 1903 had a population of 219,928.

Manila

UNIVERSITY OF THE PHILIPPINES COLLEGE OF MEDICINE AND SURGERY, Manila.—Organized in 1907 as the Philippine Medical School, under the support of the government of the Philippine Islands. Present title in 1910. The faculty numbers 53. In 1914 and thereafter two years of collegiate work leading to the degree of Bachelor of Arts will be required for admission. The course extends over five years of nine months each with an additional sixth year of intern service. The Dean is Dr. William E. Musgrave. The total registration for 1912-13 was 72; graduates, 8. The seventh session begins July 1, 1913, and ends April 2, 1914.

CANADA

The Dominion of Canada has eight medical colleges, all of which now require a four-year course, including in the first year courses in physics, chemistry and biology. This course is practically equal to that in the colleges of this country which require one year of college work for admission, including the science courses named. None of the Canadian colleges has a fixed minimum requirement of two years of collegiate work or its equivalent preliminary to or as a part of the medical course.

Manitoba

MANITOBA MEDICAL COLLEGE, Winnipeg.—It is the Medical Faculty of the University of Manitoba. Organized in 1883, first class graduated in 1886 and a class graduated each subsequent year. The faculty numbers 54. The fees are $155 for the first year and $150 for each subsequent year. The entire course covers five years, the first year including courses in physics, chemistry and biology. The Dean is Dr. H. H. Chown, 263 Broadway, Winnipeg. Total registration for 1912-13 was 154; graduates, 28. The next session begins Sept. 24, 1913, and ends May 1, 1914.

Nova Scotia

DALHOUSIE UNIVERSITY MEDICAL FACULTY, Halifax, N. S.—Organized in 1867. Incorporated as the Halifax Medical College in 1875. Reorganized as an examining faculty, separate from the Halifax Medical College in 1885. In 1911, in accordance with an agreement between the Governors of Dalhousie University and the Corporation of the Halifax Medical College, the work of the latter institution was discontinued and a full teaching faculty was established by the University. By an arrangement between Dalhousie University and the Provincial Medical Board of Nova Scotia, the final professional examinations are conducted conjointly by the University and the Board, and candidates may qualify at the same time for their academic degrees and the provincial license. First class graduated in 1872. It has a faculty of 28 professors, lecturers and demonstrators. Requires matriculation examination and a graded course of five years, including preliminary courses in physics, chemistry and biology. Fees are $100 each year. Total registration for 1912-13 was 78; graduates, 7. The Secretary is Dr. A. W. H. Lindsay, 319 Pleasant Street, Halifax, N. S. The next session begins Aug. 28, 1913, and ends April 30, 1914.

Ontario

UNIVERSITY OF TORONTO FACULTY OF MEDICINE, Toronto.—Organized 1843 as the Medical Faculty of King's College. *Abolished* in 1853. Reestablished in 1887. In 1903 it absorbed Trinity Medical College. The course of study covers five years of eight months each, the first year including courses in physics, chemistry and biology. It has a faculty of 46 professors and 107 lecturers, associates, etc., *a total* of 153. The fees are $150 each year. The Secretary is Dr. A. Primrose. The total registration for 1912-13 was 533; graduates, 85. The next session begins Sept. 30, 1913, and ends May 31, 1914.

MEDICAL FACULTY OF QUEEN'S UNIVERSITY, Kingston.—Organized 1854, first class graduated in 1855, and a class graduated each subsequent year. The faculty was originally a department of the University, but a separation took place in 1866, when the school was conducted under the charter of the Royal College of Physicians and Surgeons at Kingston. In 1892 the school again became an integral part of Queen's University. The faculty includes 25 professors and 14 assistants, instructors, etc., a total of 39. The fees amount to $105 each year; fee for M.D., C.M. degrees, $30. The course covers five years of seven months each, the first year including courses in physics, chemistry and biology. The total registration in 1912-13 was 251; graduates, 40. The Dean is Dr. J. C. Connell. The next session begins Sept. 15, 1913, and ends April 29, 1914.

MEDICAL DEPARTMENT OF WESTERN UNIVERSITY, London.—Organized in 1881, first class graduated in 1883 and a class graduated each year subsequently. The faculty numbers 30. The course is five years of seven and a half months each, the first year including courses in physics, chemistry and biology. The tuition is $100 each year. The Registrar is Dr. W. E. Waugh. Total registration for 1912-13 was 108; graduates, 27. The next session begins Sept. 17, 1913, and ends May 3, 1914.

Quebec

MEDICAL FACULTY OF McGILL UNIVERSITY.—Founded 1824 as Montreal Medical Institution; became the Medical Faculty of McGill University in 1829; first class graduated under the university auspices in 1833. No session between 1836-39 owing to political troubles. In 1905 it absorbed the Faculty of Medicine of the University of Bishop College. The course extends over five years of eight months each, including the preliminary year devoted to physics, chemistry and biology. The faculty numbers 119. The total fees are $150 for each of the first four years and $190 for the fifth. The total registration for 1912-13 was 365; graduates, 61. The Registrar is Dr. John W. Scane. The next session begins Oct. 1, 1913, and ends June 9, 1914.

LAVAL UNIVERSITY MEDICAL DEPARTMENT, Quebec.—The Quebec School of Medicine, organized in 1848, became in 1852 Medical Department of Laval University; first class graduated in 1855, and a class graduated each subsequent year. The faculty numbers 24. The fees are $60 each year. The course extends over five years, the first year including courses in physics, chemistry and biology. The Dean is Dr. Michael Joseph Ahren, Quebec. Total registration for 1912-13 was 66; graduates, 22. The next session begins Sept. 10, 1913, and ends June 1, 1914.

MONTREAL SCHOOL OF MEDICINE AND SURGERY, Montreal.—Organized in 1878 as the Medical Department of Laval University. Present name assumed in 1911. First class graduated in 1879. The faculty numbers 60. The course extends over five years. The Dean is Dr. E. P. Lachapelle. The total registration for 1912-13 was 180; graduates, 35. The next session begins Oct. 1, 1913, and ends June 20, 1914.

LIFE CHART OF MEDICAL COLLEGES

The chart shown on pages 578 to 581 shows by a series of vertical dark bands the years during which each of 308 medical colleges in the United States were in existence. Viewing the page as you open the book each of the horizontal lines represents the beginning of a year and figures for every fifth year from 1810 to 1910 are given at the right and left of each page. The five colleges organized prior to 1810 have their life lines prior to that date shown in a special section on page 580. To the right of the fourth page of the chart, figures are given following each year showing the number of colleges existing in that particular year. At the bottom of each page the name of each college is given opposite its vertical dark band and also the year it was organized and, if extinct, the year it was closed. A break in any dark band connected with a dotted line indicates that during that time the college was suspended. Such suspensions, as will be noted in the chart, were common among the medical schools of the South during the Civil War (1861-1865). Shaded lines indicate (a) that only the first two years of the medical course were offered; (b) that medical degrees were granted by the University as an examining body although no actual medical teaching was done; (c) that no degrees were granted; (d) that a preparatory course only was given; (e) that only the last two or clinical years were offered; (f) that degrees bearing the name of the university were granted for work done in another medical school, which also granted degrees; and (g) that the college was reported as not in good standing with its home state licensing board. The colleges have been so grouped as to bring together those which have been merged. The bands representing all such colleges are connected by pen lines. The grouping of the Kansas, Kentucky and Indiana colleges well illustrate this arrangement. Besides the 308 medical colleges included in this chart, there are 118 other institutions which are sometimes listed among medical schools. Among these colleges are some which apparently never held any sessions; others which had no graduates; others which, according to reports, were distinctly fraudulent or out-and-out diploma-mills; others were not legally chartered or otherwise were not recognized by their home licensing boards; others were apparently examining boards, and for others it is uncertain whether the students graduated were doctors or nurses. None of these institutions were deemed worthy of being included in the chart. A complete list[1] of these institutions follows:

IRREGULAR COLLEGES NOT INCLUDED IN CHART

ARKANSAS

Bethel Medical Department, Southwestern University, Little Rock.
Medical Department of Sulphur Rock College, Sulphur Rock.
Texas Health College, Hot Springs.*

STANDARDS OF THE COUNCIL ON MEDICAL EDUCATION OF THE AMERICAN MEDICAL ASSOCIATION

Essentials of an Acceptable Medical College

(Revised to August 1, 1913)

The following outline of the essentials of an acceptable medical college was issued by the Council on Medical Education of the American Medical Association for its suggestive value in the rapid development in progress among the medical colleges in the United States. It also represents the basis on which medical colleges are rated in the Council's classifications.

ADMISSION OF STUDENTS

1. A strict enforcement of all standards and requirements, the college itself to be held responsible for any instances in which they are not enforced.

[Since the product of the medical school depends largely on the quality of the students admitted, it is only reasonable that in its ratings hereafter, special emphasis be laid by the Council on the strictness and honesty by which the standards of admission and advanced standing are administered. By the admission of unfit students the school is handicapped from the very beginning and, in the opinion of the Council, deserves a low rating regardless of its equipment, its clinical facilities and its teaching force.]

2. A requirement for admission of at least a four-year-high-school education, and—on and after Jan. 1, 1914—in addition at least one year of college work, including at least eight semester hours each of physics, chemistry, biology and German or French.

3. These minimum requirements for admission to the study of medicine are set forth in the following statements relating (1) to the high school work and (2) to the work of the preliminary college year. The prescribed minimum of work in physics, chemistry, biology and German or French should be required by every medical school whether given in a preliminary year by the medical school itself or required in one or more years of collegiate work. The statements are as follows:

ADMISSION TO THE PRELIMINARY COLLEGE YEAR

(a) For admission to the preliminary college year, students must have completed a four-year course of at least fourteen units in a standard accredited high-school, or have its equivalent as demonstrated by an examination, and a transcript of the student's work should be secured directly from the principal of the high school by the college authorities and kept on file.

(b) The required and elective subjects for which credits for admission to the preliminary college year may be accepted are shown in the following schedule:

SCHEDULE OF SUBJECTS OFFERED IN ACADEMIC AND SECONDARY SCHOOLS, CREDITS IN WHICH ARE ACCEPTABLE FOR ENTRANCE TO THE PRELIMINARY COLLEGE YEAR LEADING TO THE MEDICAL COURSES

Total	38½	7	31½

A *unit* is the credit value of at least 36 weeks' work of 4 or 5 recitation periods per week, each recitation period to be of not less than 40 minutes. In other words, a unit represents a year's study in any subject in a secondary school constituting approximately a quarter of a full year's work. A satisfactory year's work in any subject cannot be accomplished under ordinary circumstances in less than 120 sixty-minute hours, or their equivalent.

Required Branches: Of the 14 units of high-school work the subjects in capitals aggregating 7 units are required. Other work to the amount of at least 7 units may be made up from any of the other subjects of the above schedule.

* Two units of Greek or Latin may be substituted for the two required units of French or German.

† Credentials of each science course must include evidence of laboratory work.

WORK OF THE PRELIMINARY COLLEGE YEAR

(c) The preliminary college year shall extend through one college session of at least thirty-two weeks of actual instruction, including final examinations.

(d) In excellence of teaching and in content, the work of this preliminary college year shall be equal to the work done in the freshman year in standard colleges and universities.

(e) This preliminary college year shall include courses in physics, chemistry, biology and German or French, each course to embrace at least eight semester hours of didactic and laboratory work in each subject as shown in the following schedule, provided that a student may satisfy the requirement of physics in presenting one unit of high-school physics and completing a half year of college physics which continues and does not duplicate the work done in the high school:

SCHEDULE

Subject	Lectures or Recitations Per Week	Laboratory Periods * Per Week	Total Hours Per Semester	Total Semester Hours Per Year
Physics, 1	2	2	4	8
Chemistry, 1	2	2	4	8
Biology, 1	2 or 3	2 or 1	4	8
German or French, 2	4 or 3	....	4 or 3	8 or 6
Total	10	6 or 5	16 or 15	32 or 30

* Each laboratory period must extend over at least two hours.

OR, EXPRESSED IN CLASS HOURS:

Subject	Total Hours Lectures, or Recitations	Total Hours Laboratory Work	Total Minimum Hours Didactic and Laboratory
Physics, 1	64	128	192
Chemistry, 1	64	128	192
Biology, 1	64 or 96	128 or 64	192 or 160
German or French, 2	128 or 96	... ...	128 or 96
Totals	320	384 or 320	704 or 640

(f) If a satisfactory "reading knowledge" of German or French is to be obtained in the one year of college work it is essential that an advanced course be offered and that the student have completed as a prerequisite in the high school two units of elementary work in German or French.

(g) By requiring two years of collegiate work for admission medical schools would have a greater latitude in the acceptance of high-school credentials. For example, the language requirement in the high school would not be so essential since the deficiency could easily be made up in the two years of collegiate work.

(h) It is understood, however, that a requirement of two or more years of collegiate work will not excuse the medical school from requiring the completion of a standard four-year high-school course as a prerequisite to that college work. In other words, "college work" will not be recognized as such by the Council unless the specified amount of high-school work has been required as a prerequisite

(i) It is also understood that a requirement of two or more years of collegiate work will not be considered acceptable unless courses in physics, chemistry, biology and German or French, the minimum amount of which is specified in the above table, are included.

(j) In medical colleges planning to give the work of the preliminary year, provision should be made for full-time expert teachers in the various subjects. Sufficient equipment should be provided to enable the students to do the work intelligently—in amount such as will compare favorably with the equipment for these courses in standard colleges and universities.

(k) The chief object of the work of the preliminary college year is to provide the student with a training that will enable him to enter more readily and intelligently on the study of the fundamental medical sciences in the medical school.

4. The college should require that students be in actual attendance in the college within the first week of each annual session and thereafter.

5. Actual attendance at classes should be insisted on except for good cause, such as for sickness, and under no circumstances should credit be given for any course where the attendance has been less than 80 per cent. of the full time.

6. (a) Full advanced standing may be granted to students only for work done in other acceptable colleges and in granting advanced standing there should be no discrimination against the college's full-course students. (b) Students from Class B medical schools should not be given advanced standing higher than *entrance* to the third year (junior) class and no credit should be given in any subject except on the recommendation of the head of the department teaching that subject. (c) Students from Class C colleges should not be given advanced standing higher than *entrance* to the second year (sophomore) class and then only after thorough examinations in all first year subjects have been passed. It is only in *exceptional cases* that such credit can be granted for work done in Class B and Class C colleges.

SUPERVISION, EQUIPMENT, TEACHERS

7. There should be careful and intelligent supervision of the entire school by a dean or other executive officer who holds, and has sufficient authority to carry out fair ideals of medical education as interpreted by modern knowledge.

8. There should be a good system of records showing conveniently and in detail the credentials, attendance, grades and accounts of the students by means of which an exact knowledge can be obtained regarding each student's work.

9. A fully graded course covering four years of at least 32 weeks each, exclusive of time required for matriculation and holidays, and at least 30 hours per week of actual work; this course should be clearly set forth in a carefully prepared and printed schedule of lectures and classes.

10. Two years of work consisting largely of laboratory work in thoroughly equipped laboratories in anatomy, histology, embryology, physiology, chemistry (inorganic, organic and physiologic), bacteriology, pathology, pharmacology, therapeutics and clinical diagnosis. Present day medical knowledge makes it quite essential that these subjects be in charge of full-time, thoroughly trained teachers.

11. Two years of clinical work largely in hospitals and dispensaries, with thorough courses in internal medicine (including physical diagnosis, pediatrics, nervous and mental diseases), surgery (including surgical anatomy and operative surgery on the cadaver), obstetrics, gynecology, laryngology, rhinology, ophthalmology, otology, dermatology, hygiene and medical jurisprudence.

12. As soon as conditions warrant, a fifth undergraduate year should be required which should be spent by the student as an intern in an approved hospital.

13. At least six expert, thoroughly trained professors in the laboratory branches, salaried so that they may devote their entire time to instruction and to that research without which they cannot well keep up with the rapid progress being made in their subjects. These professors should have a definite responsibility in the conduct of the college, and their first and chief interest should be in the training of the medical students. It is advised that four of these professors be placed in charge of the departments of (*a*) anatomy, (*b*) physiology, (*c*) pathology and bacteriology and (*d*) physiologic chemistry and pharmacology. The other two may be assigned one to the laboratory course in histology and embryology under the department of anatomy and the other to the department of pathology and bacteriology, possibly, to the course in laboratory clinical diagnosis. There should also be a sufficient number of assistants in each department to look after the less important details. For colleges having sixty students or less in each class, there should be at least one full-time salaried assistant for each of the four departments mentioned, and at least one additional assistant in each of these departments should be provided for each additional thirty students enrolled. This represents a low average of the full-time assistants already employed by the accepted medical colleges.

14. The faculty should be thoroughly organized and should be made up of graduates of institutions recognized as medical colleges and who have had a training in all departments of medicine. Non-medical men should be selected as teachers in medical schools only under exceptional circumstances and only because medical men of equal special capacity are not available. All faculty members should be appointed because of their ability as teachers and not because they happen to be on the attending staff of a hospital or for other like reasons.

CLINICAL FACILITIES

15. The college should own or entirely control a hospital in order that students may come into close and extended contact with patients under the supervision of the attending staff. This hospital should be in close proximity to the college and have a daily average (for senior classes of 100 students or less) of not less than 200 patients which can be utilized for clinical teaching, these patients to be of such character as to permit the student to see and study the common variety of surgical and medical cases as well as a fair number in each of the so-called specialties.

16. The college should also have ample hospital facilities for children's diseases, contagious diseases and nervous and mental diseases.

17. Facilities for at least six maternity cases for each senior student, who should have actual charge of these cases under the supervision of the attending physician. Careful records of each case should be handed in by the student.

18. Facilities for at least 30 autopsies during each college session which are attended and can be participated in by senior students (for senior classes of 100 students or less).

19. A dispensary, or out-patient department, under the control of the college, the attendance to be a daily average of 60 cases (for senior classes of 100 students or less), the patients to be carefully classified, good histories and records of the patients to be kept and the material to be well used. The attending staff should be made up of good teachers, should be well organized and be regular in attendance.

OTHER TEACHING FACILITIES

20. The college should have a working medical library to include the more modern text and reference books with the *Index Medicus* and 30 or more leading medical periodicals; the library room should be properly lighted and heated, and easily accessible to students during all or the greater part of the day; it should be equipped with suitable tables and chairs, and have a librarian in charge.

21. A working medical museum having its various anatomic, embryologic, pathologic and other specimens carefully prepared, labeled and indexed so that any specimen may be easily found and employed for teaching purposes. It is suggested that so far as possible with each pathologic specimen coming from post-mortems there also be kept the record of the post-mortem, the clinical history of the patient on whom the autopsy was held and microscopic slides showing the minute structures of the disease shown in the gross specimen.

22. There should be sufficient dissecting material to enable each student individually to dissect at least the lateral half of the human cadaver; to provide cross-sections and other demonstration material and to allow of a thorough course for each senior in operative surgery on the cadaver.

23. For modern experimental laboratory work in physiology, pharmacology and bacteriology as well as for a reasonable amount of medical research, a supply of animals—frogs, turtles, rabbits and guinea-pigs, if not also cats and dogs—is essential. Proper provision, also, is necessary for the housing and care of such animals. In any use made of animals great care should be used to prevent needless suffering and work by students should be carefully supervised.

24. A supply of such useful auxiliary apparatus as a stereopticon, a reflectoscope, carefully prepared charts, embryologic or other models, manikins, dummies for use in bandaging, a Roentgen-ray and other apparatus now so generally used in medical teaching.

25. The college should show evidences of thorough organization and of reasonably modern methods in all departments and evidences that the equipment and facilities are *being intelligently used* in the training of medical students.

26. A clear statement of the college's requirements for admission, tuition, time of attendance on the classes, sessions, courses offered and graduation should be clearly set forth, together with complete classified lists of its matriculants and latest graduating class in regular annual catalogues or announcements.

NOTE.—Correspondence from medical colleges regarding any of the above requirements is invited, and any further suggestions or information available will be gladly furnished.

Definitions of a Medical College [*] and a Medical School [†]

"An institution to be ranked as a medical college must have at least (6) professors giving their entire time to medical work, a graded course of four full years of college grade in medicine, and must require for admission not less than the usual four years of academic or high-school preparation, or its equivalent, in addition to the preacademic or grammar school studies."

By a medical school as differentiated from a medical college is meant a part of a university requiring for admission the equivalent of two years of collegiate work and offering instruction of not less than two years' duration, leading to the degree of Doctor of Medicine.

Grading of Medical Colleges

As in the previous classifications, all medical colleges were rated by the Council on Medical Education on a civil service basis on a scale of 1,000 points. The data relating to each college were grouped under ten general heads in such manner that the groups would have as nearly equal weight as possible, each group, allowing a possible 100 points (10 per cent.) out of a possible 1,000 points (100 per cent.). The ten heads under which the data were arranged are as follows:

1. Showing of graduates before state boards and other evidences of the training received.
2. Enforcement of a satisfactory preliminary educational requirement, granting of advanced standing and the character of records.
3. Character of curriculum, grading of course, length of session, time allowed for matriculation and supervision.
4. Medical school buildings; light, heat, ventilation, cleanliness.
5. Laboratory facilities and instruction.
6. Dispensary facilities and instruction.
7. Hospital facilities and instruction, maternity work, autopsies, specialties.
8. Faculty, number and qualifications of trained teachers, full-time instructors, and assistants, especially of the laboratory branches, organization, and extent of research work.
9. Extent to which the school is conducted for properly teaching the science of medicine rather than for the profit of the faculty directly or indirectly.
10. Possession and use made of libraries, museums, charts, stereopticons, etc.

Class A+ colleges are those which are acceptable; Class A those which need improvement in certain respects, but which are otherwise acceptable; Class B, those which, under their present organization, might be made acceptable by general improvements, and Class C, those which require a complete reorganization to make them acceptable.

CLASS A PLUS—ACCEPTABLE MEDICAL COLLEGES

1. *Giving an acceptable four-year course:*

California

Leland Stanford Junior Univ., Dept. of Med....San Francisco
Univ. of California, Med. Dept.....San Francisco-Los Angeles

Connecticut

Yale Medical School.............................New Haven

Illinois

Northwestern University Medical School.............Chicago
Rush Medical College (University of Chicago)........Chicago

Indiana

Indiana University School of Med...Bloomington-Indianapolis

Iowa

State University of Iowa, College of Medicine......Iowa City

Louisiana

Tulane University of Louisiana, Med. Dept......New Orleans

Maryland

Johns Hopkins University Medical Department.....Baltimore

Massachusetts

Harvard Medical School ....Boston

Michigan

University of Michigan, Dept. of Med. and Surg....Ann Arbor

Minnesota

University of Minnesota, Coll. of Med. and Surg...Minneapolis

Missouri

Washington University Medical School..............St. Louis

New York

Columbia University Coll. of Phys. and Surgs..New York City
Cornell University Medical College............New York City
University and Bellevue Hospital Med. Coll....New York City
Syracuse University, College of Medicine............Syracuse

Ohio

Ohio-Miami Med. Coll. of the Univ. of Cincinnati....Cincinnati
Western Reserve University Medical Department....Cleveland

Pennsylvania

University of Pennsylvania, Dept. of Medicine...Philadelphia

Texas

University of Texas, Department of Medicine.......Galveston

Virginia

University of Virginia, Department of Med....Charlottesville

2. *Giving a two-year course acceptably:*

Missouri

University of Missouri, School of Medicine..........Columbia

Wisconsin

University of Wisconsin, College of Medicine........Madison

Total 24.

CLASS A.—COLLEGES LACKING IN CERTAIN RESPECTS BUT OTHERWISE ACCEPTABLE

1. *Giving a complete four-year course:*

Alabama

University of Alabama, School of Medicine.............Mobile

Colorado

University of Colorado, School of Medicine....Boulder-Denver

District of Columbia

Georgetown University School of Medicine.......Washington
George Washington University, Dept. of Medicine..Washington
Howard University, School of Medicine...........Washington

Georgia

University of Georgia, College of Medicine[1]..........Augusta

Illinois

College of Physicians and Surgeons...................Chicago

Iowa

Drake University College of Medicine[2]...........Des Moines
State University of Iowa, Homeopathic College....Iowa City

Kansas

University of Kansas, School of Medicine...Lawrence-Rosedale

Kentucky

University of Louisville, Medical Department......Louisville

Maine

Medical School of Maine................Brunswick-Portland

---

[*] This definition of a college is based on that given in the revised ordinances of the state of New York. It has been adopted also by the Carnegie Foundation for the Advancement of Teaching.

[†] Based on the definition of the term "school" adopted in 1909 by the Association of American Universities.

[1] Rating changed to Class A, Feb. 24, 1913

[2] Merged with the State University of Iowa College of Medicine in 1913.

Maryland

Baltimore Medical College[3]	Baltimore
College of Physicians and Surgeons	Baltimore
University of Maryland, School of Medicine	Baltimore

Massachusetts

Boston University School of Medicine	Boston
Tufts College Medical School	Boston

Michigan

University of Michigan, Homeopathic College	Ann Arbor

Missouri

Jefferson Medical College	Philadelphia
Medico-Chirurgical College of Philadelphia	Philadelphia
Woman's Medical College of Pennsylvania	Philadelphia
University of Pittsburgh, School of Medicine	Pittsburgh

Tennessee

Meharry Medical College	Nashville
Vanderbilt University, Medical Department	Nashville

Vermont

University of Vermont, College of Medicine	Burlington

Virginia

Medical College of Virginia[4]	Richmond
University College of Medicine[4]	Richmond

2. *Giving a two-year course:*

Mississippi

University of Mississippi, Medical Department	Oxford

North Carolina

University of North Carolina, School of Medicine	Chapel Hill
Wake Forest College, School of Medicine	Wake Forest

North Dakota

University of North Dakota, College of Medicine	University

South Dakota

University of South Dakota, College of Medicine	Vermilion

Utah

University of Utah, School of Medicine	Salt Lake City

Total 42.

CLASS B.—COLLEGES NEEDING GENERAL IMPROVEMENTS TO BE MADE ACCEPTABLE

1. *Giving a complete four-year course:*

Alabama

Birmingham Medical College[5]	Birmingham

Arkansas

University of Arkansas, Medical Department	Little Rock

California

College of Physicians and Surgeons	Los Angeles
Hahnemann Medical College of the Pacific	San Francisco
Oakland College of Medicine and Surgery	Oakland

Georgia

Atlanta College of Physicians and Surgeons[6]	Atlanta
Atlanta School of Medicine[6]	Atlanta

Illinois

Bennett Medical College	Chicago
Chicago College of Medicine and Surgery	Chicago
Hahnemann Medical College and Hospital	Chicago

Kansas

Kansas Medical College[7]	Topeka

Michigan

Detroit College of Medicine	Detroit

Missouri

University Medical College[8]	Kansas City

Southern Methodist University Medical Department	Dallas

WISCONSIN

Milwaukee Medical College[19]	Milwaukee
Wisconsin College of Physicians and Surgeons[20]	Milwaukee

Note.—Official statements from the following state licensing boards indicate that as a rule the colleges rated in Class C are not recognized:

Alabama
Arkansas (Reg.)
Colorado
Connecticut (Reg.)
Delaware
Indiana
Iowa
Kentucky
Louisiana (Reg.)
Maryland (Reg.)
Michigan
Minnesota
New Hampshire
New Jersey
New Mexico
North Dakota
Ohio
Pennsylvania
Rhode Island
Texas
Vermont
Virginia
West Virginia
Wisconsin

Colleges and States Having Higher Entrance Requirements

The thirty-two medical schools which are now requiring as a minimum for entrance two or more years of work in a college of liberal arts in addition to a four-year high-school education are as follows:

College	Began
Johns Hopkins University, Medical Department	1893
Harvard Medical School	1900
Western Reserve University School of Medicine	1901
University of Chicago, Rush Medical College	1904
University of California, Medical Department	1905
University of Minnesota Medical School	1907
University of North Dakota, College of Medicine	1907
University of Wisconsin, College of Medicine	1907
Cornell University Medical College	1908
Wake Forest College, School of Medicine	1908
Leland Stanford Junior University, Department of Medicine	1909
Yale Medical School	1909
University of Kansas, School of Medicine	1909
University of Michigan, College of Medicine	1909
University of Nebraska, College of Medicine	1909
University of South Dakota, College of Medicine	1909
University of Colorado, School of Medicine	1910
Indiana University School of Medicine	1910
State University of Iowa, College of Medicine	1910
State University of Iowa, College of Homeopathic Medicine	1910
Drake University, College of Medicine	1910
University of Missouri, Department of Medicine	1910
Dartmouth Medical School	1910
Columbia University College of Physicians and Surgeons	1910
Syracuse University College of Medicine	1910
University of Pennsylvania, Medical Department	1910
University of Utah, Medical Department	1910
Northwestern University Medical School	1911
Georgetown University School of Medicine	1912
Washington University Medical School	1912
Ohio-Miami Medical College, Univ. of Cincinnati	1913
University of Pittsburgh, School of Medicine	1913

The following seven medical schools have announced the adoption of the two-year collegiate requirement to take effect in the year given:

University of Georgia, College of Medicine	1914
University of Illinois, College of Medicine	1914
University [illegible] Department	1914
Fordham [illegible] Medicine	1914
University [illegible] of Medicine	1915
College of [illegible] Loma Linda, Cal	1915
Marquette [illegible] of Medicine	1915

The twenty-one following colleges require, in addition to a four-year high-school course, one year of college work in physics, chemistry, biology and a modern language, the requirement beginning in the year given:

College	In Force
Howard University, School of Medicine	1910
Tulane University, School of Medicine	1910
St. Louis University, School of Medicine	1910
University of North Carolina, School of Medicine	1910
University of Oregon, Medical Department	1910
University of Texas, Medical Department	1910
University of Virginia, Department of Medicine	1910
West Virginia University, School of Medicine	1911
Medical School of Maine	1912
University of Michigan, Homeopathic College	1912
University and Bellevue Hospital Medical College	1912
Leonard Medical School	1912
University of Vermont, College of Medicine	1912
University of Illinois, College of Medicine	1913
Cleveland-Pulte Medical College	1913
Hahnemann Medical College, Philadelphia	1913
Jefferson Medical College	1913
Medico-Chirurgical College of Philadelphia	1913
Temple University, [illegible]	1913
Woman's Medical [illegible]	1913
Baylor University, [illegible]	1913

The twenty-one following medical colleges have intimated that, beginning in 1914, they will require for admission, in addition to a standard four-year high-school education, the premedical college year devoted to courses in physics, chemistry, *biology and a modern language:*

College	In Force
College of Physician [illegible] Angeles	1914
Oakland College of [illegible]	1914
George Washington [illegible] Department	1914
Bennett Medical College	1914
College of Physicians and Surgeons, Baltimore	1914
University of Maryland, School of Medicine	1914
Boston University, School of Medicine	1914
Tufts College Medical School	1914
Detroit College of Medicine	1914
University of Mississippi, Medical Department	1914
John A. [illegible] College	1914
Albany [illegible]	1914
Long Is [illegible]	1914
University of Buffalo, Medical Department	1914
Starling-Ohio Medical College	1914
State University of Oklahoma, School of Medicine	1914
Vanderbilt University Medical Department	1914
University of Tennessee, Department of Medicine	1914
Fort Worth School of Medicine	1914
Southern Methodist University, Medical Department	1914
Medical College of Virginia	1914

After Jan. 1, 1914, therefore, there will be seventy-one medical colleges which will have put into effect entrance requirements of at least one year of college work including courses in physics, chemistry, biology and a modern language.

Higher Preliminary Requirements by State Boards

There are now thirteen state medical licensing boards which have adopted preliminary requirements in advance of a four-year high-school education. These are as follows:

State Examining Board of	No. of Years Required.	Affects Students Matriculating.	Affects all Applicants.
North Dakota	2	1907-08	1911
Iowa	2	1907-08	1911
Minnesota	2	1908-09	1912
Colorado	2	1910-11	1914
Connecticut	1	1910-11	1914
Kansas	1	1910-11	1914
Indiana	2	1910-11	1914
Utah	1	1910-11	1914
South Dakota	2	1911-12	1915
Vermont	1	1912-13	1916
Pennsylvania	1	1913-14	1917
Kentucky	2	1914-15	1918
California	1	1914-15	1918

---

[15] Reported not in good standing by the Missouri State Board of Health.

[16] This college will close when the senior class now enrolled has been graduated.

[17] Not included among fully registered colleges in the list issued by the New York Education Department, October, 1912. Reported suspended same year.

[18] Merged with the *University of Oregon Medical Department* at Portland.

[19] This college was closed *in December, 1912, and its property* leased to Marquette University.

[20] In December, 1912, the property of this school was transferred to Marquette University, which is developing a new school of medicine.

The Association of American Medical Colleges

The requirements for admission to and graduation from colleges holding membership in this association are as follows:

SECTION 1.—Every college holding membership in this Association shall, on and after Jan. 1, 1912, require for matriculation a completed or unconditioned medical student's certificate, to be granted by a state medical examining and licensing board, or a board empowered by statute to grant such certificates, or a certificate of entrance to the academic department of any state university, or a certificate of entrance to an accredited university or college, providing that said certificate is granted on no less than the following requirements:

(*a*) A bachelor's degree from an accredited college or university.

(*b*) A diploma and transcript of record from a fully accredited high school, normal school or academy requiring for admission evidence of the completion of a standard course in primary and intermediate grades, and for graduation, the completion of a standard four-year high-school course, embracing two years (2 units) of mathematics, two years (2 units) of English, two years (2 units) of one foreign language, one year (1 unit) of American history and civics, and seven years (7 units) of further credit in language, literature, history or science, making the total of units at least fourteen; *and in addition, one year each of physics, chemistry and biology of college grade of each not less than six semester hours.*

(*c*) An examination in the following branches totalling 14 units:

(A) Required, 7 units.	Units.
Mathematics (minimum 2 years, maximum 3 years), algebra and plane geometry	2
English (minimum 2 years, maximum 4 years)	2
One foreign language (minimum 2 years, maximum 4 years)	2
History (U. S.) and civics	1
Total number of required units	7

(B) Elective, 7 units.
To be selected from the following:

	Units.
English language and literature (in addition to the required work)	1 *to* 2
Foreign languages, additional, Latin, German, Italian, French, Spanish or Greek (not less than 1 year in any one)	1 to 4
Advanced mathematics, advanced algebra, solid geometry and trigonometry (½ year each)	1
Natural science, chemistry 1 year, physics 1 year, and biology, botany, physiology and zoology (½ to 1 year each)	½ to 2
Earth science, physical geography, geology and agriculture (½ year to 1 year each)	½ to
Astronomy (½ year)	½
Drawing (½ to 1 year)	½ to 1
History, ancient, medieval and modern, and English (1 year each)	1 *to* 3
Economics (½ year)	½
Manual training (1 year)	1
Book-keeping (½ to 1 year)	½ to 1

And in addition one year each of physics, chemistry and biology of college grade, of each not less than 8 semester hours.

One unit in any subject is the equivalent of work in that subject *for four or five periods per week for a year of at least thirty-six weeks*, periods to be not less than forty-five minutes in length. One unit is equivalent to 2 semester credits or 2 points.

THE PRELIMINARY COLLEGE YEAR

At a joint meeting of the committees representing the Association of American Medical Colleges and the Council on Medical Education of the American Medical Association held March 22, 1913, and with the advice of Dr. *Kendric C. Babcock*, Specialist in Higher Education of the United States Bureau of Education, the following requirements were adopted for the preliminary college year:

(*a*) The preliminary college year shall extend through one college session of at least thirty-two weeks of actual instruction, including final examinations.

(*b*) In excellence of teaching and in content, the work of this preliminary college year shall be equal to the work done in the freshman year in standard colleges and universities.

(*c*) This preliminary college year shall include courses in physics, chemistry, biology and German or French, each course to embrace at least eight semester hours of didactic and laboratory work in each subject as shown in the following schedule, provided that a *student* may satisfy the requirement of physics in presenting one unit of high-school physics and completing a half year of college physics which continues *and does* not duplicate the work done in the high school:

SCHEDULE

Subject	Lectures or Recitations Per Week	Laboratory Periods * Per Week	Total Hours Per Semester	Total Semester Hours Per Year
Physics, 1	2	2	4	8
Chemistry, 1	2	2	4	8
Biology, 1	2 *or* 3	2 or 1	4	8
German or French, 2	4 or 3	......	4 or 3	8 or 6
Total	10	6 or 5	16 or 15	32 or 30

* Each laboratory period must extend over at least two hours.

OR, EXPRESSED IN CLASS HOURS:

Subject	Total Hours Lectures, or Recitations	Total Hours Laboratory Work	Total Minimum Hours Didactic and Laboratory
Physics, 1	64	128	192
Chemistry, 1	64	128	192
Biology, 1	64 or 96	128 or 64	192 or 160
German or French, 2	128 or 96	....	128 or 96
Totals	320	384 or 320	704 or 640

(*d*) In *medical* colleges planning to give the work of the preliminary year, provision should be made for full-time expert teachers in the various subjects. Sufficient equipment should be provided to enable the students *to do* the work *intelligently*—in amount such as will compare favorably with the equipment for these courses in *standard* colleges and universities.

(*e*) It should be *remembered that the chief object* of the work of the preliminary college year is to provide the student with a *training* that will enable him to enter more readily and intelligently on the study of the fundamental medical sciences in the medical school.

SEC. 2.—This examination must be conducted by or under the authority of the board of medical examiners of the state in which the college is located, or by a duly authorized examiner of the college entrance *examination board*, or the *authorized examiner of* an accredited university, state or otherwise, or by an examiner whose certificates are accepted by accredited colleges or universities, or by a method approved by the judicial council of this association.

SEC. 3.—The term "accredited" as applied to high schools, academies, colleges and universities means institutions of that type that have been investigated and are accredited by the state *university of their respective states*, by the North Central Association of Colleges and Secondary Schools, the *Association of* Colleges and Preparatory Schools of the Southern States, the Association of Colleges and Preparatory Schools of the Middle States and Maryland, the New England College Entrance Certificate Board, the Association of American Universities and the Association of State Universities, *provided* that such accrediting is based on Article III, Section 1, of this constitution.

SEC. 4.—Colleges in membership in this Association may honor the official credentials *presented* by students from other colleges having the standard requirements maintained by members of this Association, excepting for the fourth year of the course, *but no* member of this Association shall admit a student to advanced *standing* without receiving from the dean, secretary or registrar of such college a direct written communication certifying to the applicant's standing. Credit for time or scholarship cannot be *given beyond that of the college issuing the credentials*, except by mutual agreement between the colleges.

SEC. 5.—*Candidates for* the degree of Doctor of Medicine shall *have attended four courses of* study in four calendar years, each annual course to have been of not less than thirty-two teaching weeks' duration, and at least ten months shall intervene between the beginning of any course and the beginning of the preceding course.

SEC. 6.—No *time* credit shall be given to holders of a Bachelor's degree, but subject credit may be given on satisfactory examination. Four years of residence in a medical college shall be required *of all* candidates for the degree of Doctor of Medicine.

SEC. 7.—A college which gives less than a four years' course of study, but does not graduate students, and is possessed of other *required qualifications*, may be admitted to membership.

SEC. 8.—Each student shall be obliged to attend not less than 80 per cent. of the exercises in every annual course of study for which he seeks *credit*. No student shall be given credit on examination unless he attains a grade of at least 70 per cent. or its equivalent in any other marking system. And no student shall be graduated unless he shall have attained a passing grade in each and all subjects of the required curriculum.

CURRICULUM

SECTION 1.—The entire course of four years shall consist of at least 4,000 hours for each student, and shall be grouped in divisions and subdivided into subjects; each division and subject to be allotted the number of hours as shown in the following schedule:

DIVISION 1.—ANATOMY, 720 Hours (18 per Cent.)

	Hours.	Lect. Rec. Dem.	Lab. Wk.
(a) Gross anatomy (including applied anatomy)	510	120	390
(b) Histologic and microscopic anatomy	135	30	105
(c) Embryology	75	30	45

DIVISION 2.—PHYSIOLOGY AND CHEMISTRY, 600 Hours (15 Per Cent.)

	Hours.	Lect. Rec. Dem.	Lab. Wk.
(a) Inorganic chemistry	180	60	120
(b) Organic chemistry	75	30	45
(c) Physiologic chemistry	104	30	75
(d) Physiology	240	140	100

DIVISION 3.—PATHOLOGY, BACTERIOLOGY AND HYGIENE, 450 Hours (11.25 Per Cent.)

	Hours.	Lect. Rec. Dem.	Lab. Wk.
(a) Bacteriology	135	80	105
(b) Hygiene and general dietetics	45	45	...
(c) Pathology	270	60	210

DIVISION 4.—PHARMACOLOGY, MATERIA MEDICA AND THERAPEUTICS, 240 Hours (6 Per Cent.)

	Hours.	Lect. Rec. Dem.	Lab. Wk.
(a) Pharmacology	105	40	65
(b) Materia medica and pharmacology	80	...	...
(c) Therapeutics	55	...	...

DIVISION 5.—MEDICINE AND MEDICAL SPECIALTIES, 970 Hours (24.25 Per Cent.)

	Hours.	Lect. Rec. Dem.	Lab. Wk.
(a) General medicine (including clinical microscopy)	640	...	...
(b) Pediatrics	150	...	...
(c) Nervous and mental diseases	105	...	...
(d) Jurisprudence, ethics and economics	30	...	...
(e) Dermatology and syphilis	45	...	...

DIVISION 6.—SURGERY AND SURGICAL SPECIALTIES, 720 Hours (18 Per Cent.)

	Hours.	Lect. Rec. Dem.	Lab. Wk.
(a) General surgery	510	...	...
(b) Orthopedic surgery	45	...	...
(c) Genito-urinary diseases	45	...	...
(d) Eye	60	...	...
(e) Ear, nose and throat	60	...	...

DIVISION 7.—OBSTETRICS AND GYNECOLOGY, 300 Hours (7.5 Per Cent.)

	Hours.	Lect. Rec. Dem.	Lab. Wk.
(a) Obstetrics	195	...	...
(b) Gynecology (including some abdominal surgery)	105	...	...

Colleges may reduce the number of hours in any subject not more than 20 per cent. provided that the total number of hours in a division is not reduced. Where the teaching conditions in a college are best subserved, the subject may be, for teaching purposes, transferred from one division to another. When didactic and laboratory hours are specified in any subject, laboratory hours may be substituted for didactic hours.

SEC. 2.—Each medical college in membership in the Association shall print in every annual catalogue or announcement a table of the total number of hours work given in said college, arranged both by subjects and years.

SEC 3.—Each college in membership in this Association shall print annually a list of its students by classes.

MEMBERS OF ASSOCIATION

University of Alabama, School of Medicine.
Leland Stanford Junior University, *Department of Medicine.*
University of California, Medical Department.
University of Southern California, Medical Department.
University of Colorado, School of Medicine.
Yale Medical School.
Georgetown University, School of Medicine.
George Washington University, Department of Medicine.
Howard University, Medical Department.
University of Georgia, College of Medicine.
Northwestern University, Medical School.
Rush Medical College.
University of Illinois, College of Medicine.
Indiana University, School of Medicine.
State University of Iowa, College of Medicine.
University of Kansas, School of Medicine.
University of Louisville, Medical Department.

University of Missouri, School of Medicine.
Washington University, Medical School.
John A. Creighton Medical College, Medical Department.
University of Nebraska, College of Medicine.
College of Physicians and Surgeons, Columbia University.
Cornell University Medical College.
Syracuse University, College of Medicine.
University and Bellevue Hospital Medical College.
University of Buffalo, Medical Department.
University of North Carolina, Department of Medicine.
Wake Forest College, School of Medicine.
University of North Dakota, College of Medicine.
Ohio-Miami Medical College of the University of Cincinnati.
Starling-Ohio Medical College.
Western Reserve University, School of Medicine.
State University of Oklahoma, School of Medicine.
Hahnemann Medical College and Hospital, Philadelphia.
University of Pennsylvania, Medical Department.
University of the Philippines, College of Medicine and Surgery.
University of Pittsburgh, School of Medicine.
Meharry Medical College.
Vanderbilt University, Medical Department.
University of Texas, Medical Department.
University of Utah, Department of Medicine.
University of Vermont, College of Medicine.
Medical College of Virginia.
University of Wisconsin, College of Medicine.

The secretary-treasurer of the Association is Dr. Fred C. Zapffe, 3431 Lexington Street, Chicago.

STATE BOARD NOTES

New Medical Practice Acts.—New medical practice acts have been recently secured for Alaska, Arizona, California, Georgia, Michigan and Pennsylvania. The new practice act of California provides for a year of collegiate work as the minimum standard of preliminary education for all applicants in 1918 and thereafter. The new law of Georgia does away with three separate sectarian boards, replacing them with a single board having on it representatives of all the "schools" of medicine. The new practice act of Pennsylvania requires a year of college work in physics, chemistry and biology in addition to a four-year high-school education, and also requires that before he is eligible to take the license examination the graduate must have served an internship in an approved hospital.

Class C Colleges not Recognized.—At a recent meeting, the New Mexico State Board of Medical Examiners adopted a resolution that hereafter colleges rated in Class C by the Council on Medical Education will not be considered in good standing with that board. This makes twenty-five state boards which have adopted such measures.

New Federation of State Medical Boards.—The organization of a new Federation of State Medical Boards was completed last February and it has a great opportunity for good. A uniformly high but fair standard upheld in all states will make it easier to establish reciprocity between all states. But standards at present are far from uniform and in some states adequate barriers to protect the public against incompetent doctors, quacks and impostors do not exist. To bring about better safeguards against these evils is a very important work. The remarkable improvements made in recent years among medical colleges reveals in stronger contrast the great need of improvements in medical licensure. In no state are the requirements for the license as strict as in the majority of European countries. In no state is the license examination so severe as that of Germany, or that given by the Conjoint Board of England. And no organization is better situated to bring about improvements in medical licensure in this country than is the new Federation of State Medical Boards.

State University Medical Schools

Twenty-seven states now have medical schools as integral parts of the state universities or—in one instance—under state control as separate institutions. These states and other interesting data regarding the medical schools are as follows:

STATE UNIVERSITY MEDICAL SCHOOLS

Medical School of State University of	Only School in State	Length of Med. Course in Years.	Years of College Work for Admission.	Medical School of State University of	Only School in State.	Length of Med. Course in Years.	Years of College Work for Admission.
Alabama	1915	4	..[2]	North Carolina	......	2	1
Arkansas	Yes	4	....	North Dakota	Yes	2	2[3]
California	......	4	2	Oklahoma	Yes	4	....
Colorado	Yes	4	2[3]	Oregon	Yes	4	1

[illegible]	[illegible]	2	....	Wisconsin	......	2	2
Nebraska	......	4	2				

* Have Homeopathic Departments.
1. To require 2 years in 1914.
2. To require 2 years in 1915.
3. Similar requirement by Licensing Board.

In fifteen states no other medical schools exist, medical education in the state being entirely in charge of the state university. This will be true in Alabama also in 1915, when an independent medical school now existing will give only post-graduate instruction.

H., Homeopathic; E., Eclectic

REFERENCES TO TABLE 1.

(a) These two colleges have merged, taking the name of Atlanta Medical College.

(b) This college has been closed.

(c) The Jenner Medical College is reported to be not fully recognized by twenty-nine different state licensing boards.

(d) This college has merged with the State University of Iowa College of Medicine and Surgery.

(e) This college has merged with the University of Kansas School of Medicine.

(f) This college has merged with the University of Maryland School of Medicine.

(g) This college is reported to have closed.

(h) The approximate number of medical students actually attending is given; the college reported 181 "matriculants and applicants" which include also the dental classes. This college is reported as not recognized by the Massachusetts Medical Society.

(i) This college gave only the last two, or clinical years of the medical course. It is reported to have closed.

(j) This college is reported as not recognized by the Missouri State Board of Health and by twenty other state licensing boards.

(k) This college will close next year when the one class still enrolled will be graduated.

(l) Dartmouth Medical School will discontinue teaching the clinical years after the class of 1914 has graduated.

(m) This college merged with Western Reserve University School of Medicine in 1910, with the understanding that all classes then enrolled would receive their degrees from the former college. This year the last class received degrees.

(n) This college has merged with the University of Oregon, Medical Department.

(o) This college has merged with the University of Tennessee, Medical Department.

(p) This college and the Medical College of Virginia have been merged, retaining the name of the latter.

(q) Two years ago this institution was closed as a "College of Medicine" but was later restored as a "School." It is stated there was no intention to discontinue medical teaching.

(r) This is a new medical school, an integral part of Marquette University, formed by purchase of the property of the Wisconsin College of Physicians and Surgeons and by lease of the property of the Milwaukee Medical College, both of these institutions having been closed.

(s) The fees charged by this college are only $80 per year for citizens of the state. Similar reductions are made by the medical schools of the University of Michigan, for residents of that state.

(t) This college is financed by the government and no tuition fees are charged.

(u) All the Canadian medical schools now have a "five-year medical course," but this includes a preliminary year devoted largely to courses in physics, chemistry and biology. It is the equivalent therefore to the courses given by the medical schools in the United States which require for admission one year of collegiate work including the sciences mentioned. On the same basis medical colleges in the United States which require two or more years of collegiate work for admission may be said to require a six-year course, or, if the hospital intern year be added, a seven-year course.

Of the twenty-seven state medical schools, twenty give the complete medical course and grant M.D. degrees while seven give only the first two years of the medical course. Minnesota now requires a five-year course, the fifth year to be spent by the student in a hospital as an intern, or in other recognized clinical work. The universities of Iowa and Michigan have Homeopathic departments. In Iowa the entrance requirements are the same for the two departments but in Michigan, while for the regular department two years of collegiate work are required for entrance, only one year is required for the Homeopathic College; nevertheless, the students of the two colleges are taught together in the work of the first two years.

As may be noted, thirteen of these state university medical schools are now requiring for admission two years of collegiate work. The medical schools of the Universities of Georgia and Illinois have adopted the two-year requirement to become effective in 1914. The medical school of the University of Alabama has announced the two-year requirement to take effect in 1915. As already shown the state schools are supported in this requirement by the state licensing boards in Colorado, Indiana, Iowa, Minnesota, North Dakota and South Dakota. Of the fourteen other state university medical schools eight are still requiring for admission a standard four-year high-school course and six are requiring in addition one year of collegiate work.

The Combined Course in Liberal Arts and Medicine

There are fifty medical schools which announce that arrangements have been made whereby students can secure degrees in both arts and medicine in six or seven years' time. Many have arranged for the B.S. and M.D. degrees in six years, or the A.B. and M.D. degrees in seven years. The list of medical schools follows:

College	*B.S. and M.D.*	*A.B. and M.D.*
University of Alabama, School of Medicine	6	7
Leland Stanford Junior University, Dept. of Med.	..	7

COLLEGE NOTES

Colleges Closed During the Year.—Fourteen medical colleges have been closed during the year. Eight were closed by merger into other medical schools and six became extinct. The colleges are:

Atlanta College of Physicians and Surgeons and the Atlanta School of Medicine merged taking the name of the Atlanta Medical College.

Hering Medical College, Chicago, reported closed.

Drake University College of Medicine, Des Moines, Iowa, merged into the State University of Iowa, College of Medicine.

Kansas Medical College Topeka, merged into the University of Kansas School of Medicine.

Baltimore Medical College, merged with the University of Maryland School of Medicine.

Maryland Medical College, reported closed.

University Medical College, Kansas City, Missouri, reported closed.

Eclectic Medical College of the City of New York, reported closed.

Willamette University Medical Department, Salem, Oregon, merged with the University of Oregon, Medical Department at Portland.

Memphis Hospital Medical College, merged with the University of Tennessee College of Medicine.

University College of Medicine, Richmond, merged with the Medical College of Virginia.

Milwaukee Medical College, closed.

Wisconsin College of Physicians and Surgeons, closed.

* Information showing exact distribution not obtained. † Number of students approximate. H.—Homeopathic. E.—Eclectic.

New Colleges.—The Atlanta Medical College was formed by the merger of the Atlanta College of Physicians and Surgeons with the Atlanta School of Medicine. The Marquette University, Milwaukee, Wis., organized its new School of Medicine by taking over the Wisconsin College of Physicians and Surgeons and the Milwaukee Medical College. The Homeopathic College of the State University of Iowa has been reestablished. In Chicago another "afternoon and evening" medical college has been started called the Chicago Hospital College of Medicine, but, according to an official statement, has not yet secured recognition as being in good standing with the Illinois State Board of Health. At Los Angeles, California, an institution calling itself the Pacific Medical College and Post-Graduate Medical School has been organized but makes a boast of granting credit to practitioners of "drugless therapy" which apparently classifies it among such institutions. At Baltimore a new college was organized, at first called the Eclectic School of Medicine of Milton University. After a short time Milton University is said to have disclaimed any relationship with it, and the name was changed to Eastern University School of Medicine. It has been reported as not recognized by the Maryland State Board of Medical Examiners.

Endowments, New Buildings and Other Incidents Occurring During the Year

Alabama.—The University of Alabama School of Medicine, Mobile, has refused promotion to students who failed to pass all examinations, feeling that students promoted with conditions were doubly handicapped. The action will doubtless have a wholesome effect on the scholarship in that school.

——Birmingham Medical College has transferred all its property to the University of Alabama and will be converted into a graduate school of medicine.

Arkansas.—The University of Arkansas, Medical Department, was granted an appropriation of $36,000 by the legislature for the biennium ending March 31, 1915.

California.—The University of California received $1,000,000 from Mrs. George William Hooper to establish an institute of medical research, in memory of her husband. Another gift of $150,000 was received from John M. Keith for a medical research teaching hospital as a memorial to his wife. Gifts to the amount of $400,000 were also assured to build and equip new departments of the University Hospital. It is proposed to move all four years of the medical course to San Francisco and to place the clinical department on an academic basis. A summer course for graduate students has been established.

——Leland Stanford Junior University College of Medicine dedicated the new Lane Medical Library, Nov. 3, 1912. This is a beautiful structure across the street from the medical college building in which the library was formerly located. Since the transfer of the library to the new building, about $35,000 have been expended in reconstructing the medical building, providing for more laboratories and more space for the out-patient department. A fifth year to be devoted to intern work will be required for the M.D. degree for those entering the session of 1914-15 and thereafter.

——The Los Angeles Medical Department of the University of California has received an appropriation of $45,000 from the State Board of Control of California.

Connecticut.—Yale Medical School received $25,000 from the estate of Cyprian S. Brainerd.

Georgia.—*The new medical building of the University of* Georgia Medical Department of Augusta was dedicated Jan. 29, 1913. A special course in public health is to be offered and special degrees will be granted to those completing the course.

Illinois.—The University of Illinois has again taken over the College of Physicians and Surgeons of Chicago, this time as a gift from the alumni. The legislature voted an appropriation of $200,000 for two years for its development.

——Rush Medical College has voted to make obligatory for all students entering in 1914 and thereafter, the five-year course including a year as intern in an approved hospital or in other special clinical or laboratory work. This course has been optional since 1905.

——Hahnemann Medical College of Chicago announces subscriptions of $66,460 toward a permanent endowment fund.

Indiana.—The Indiana University received $65,000 for the Medical School and the Robert W. Long Memorial Hospital for the next year and $75,000 annually thereafter. Another gift of $25,000 was received from Dr. Robert W. Long for completing and furnishing the hospital bearing his name. The contract for building this hospital was let for $161,000 and the construction is now well under way.

Louisiana.—Tulane University has enlarged its Medical Department, which is now called the "College of Medicine." It comprises the School of Medicine, School of Tropical Medicine and Graduate School of Medicine.

Maryland.—Johns Hopkins Hospital has had several important additions. The Harriet Lane Home for Children erected at a cost of $300,000; the James Buchanan Brady Urologic Clinic from a gift of $200,000 from Mr. Brady, who has since agreed to give $15,000 annually for maintenance; Mr. William A. Marlburg has made a substantial addition to the gift of

$100,000 from him and the other heirs of Charles L. Marlburg to erect a memorial hospital building of fifty-four rooms for private patients.

——Johns Hopkins Medical School has fixed a limit of about ninety students for each class, owing to the limited space and facilities in the various laboratories. Yet the space equipment and facilities are greater than in several other colleges which have not seen any necessity for limitations.

——The University of Maryland School of Medicine received $5,300 from Dr. and Mrs. J. C. Hemmeter toward an endowment fund for the chair of physiology.

Massachusetts.—Harvard Medical School received $50,000 by the will of Abel H. Proctor as an addition to the Ellen Osborn Proctor fund for the study of chronic diseases.

Minnesota.—The University of Minnesota has changed the name of its "College of Medicine" to "Medical School," and the faculty has undergone a complete reorganization.

Missouri.—To Washington University School of Medicine has been given the Pagel collection of books on the history of medicine, comprising 2,500 titles. The new hospital and medical school buildings are rapidly approaching completion.

——St. Louis University School of Medicine is erecting a new three-story addition to its college building at a cost of approximately $10,000, to be occupied by the college office and library and for laboratories for experimental medicine.

New Hampshire.—Dartmouth Medical School has voted to discontinue clinical teaching after the graduation of the class of 1914. This is in recognition that clinical teaching in future will require a larger amount of clinical material than is available at Hanover.

New York.—Albany Medical College has been given a new site near the Albany General Hospital where it is planned to erect a new college building.

——Cornell University Medical College has formed a close affiliation with the New York Hospital. A substantial fund for this purpose was provided by Mr. George F. Baker. Cornell also receives from another donor $1,000 annually for a fellowship in the New York Hospital.

——Columbia University received a gift of $1,566,000 by the will of Mr. George Crocker for a cancer research fund.

——University and Bellevue Hospital Medical College received $25,000 from Mrs. Helen Hartley Jenkins, completing the $100,000 endowment fund for the Marcellus Hartley chair of Medicine.

——Fordham University has completed a new building for its School of Medicine at a cost of $250,000.

Nebraska.—The entire four-year course of the University of Nebraska College of Medicine is to be moved to the new medical building in Omaha.

——The John A. Creighton Medical College has received $1,000 toward the endowment of the medical library and an additional sum of $200 annually for maintenance.

Ohio.—Ohio-Miami Medical College of the University of Cincinnati received $125,000 from Mrs. Mary Emery toward the million dollar endowment for the department of pathology. For the endowment of another chair $80,000 was received from the estate of Dr. Francis Brunning. An endowment fund of $50,000 was also received, to be known as the Julie Fries Levy Endowment, the income of which is to be used to further and disseminate medical knowledge. Plans are being laid to secure the needed funds ($250,000) for the erecting of a new medical college building opposite the new Cincinnati City Hospital. It is intended as a memorial to Dr. Daniel Drake, the father of medicine in Ohio.

Oregon.—The Medical Department of the University of Oregon secured an appropriation of $45,000 from the state legislature.

Pennsylvania.—The University of Pennsylvania is erecting a new surgical building at a cost of approximately $300,000. A gift of $50,000 (source not reported) was received to be used to provide for additional hospital beds. The will of Dr. Louis A. Duhring gives $81,000 to the University and its hospital, the income from which is to be used for a department of cutaneous diseases, for scholarships and research along that line and for free beds for such diseases in the University Hospital.

——Jefferson Hospital received $50,000 (source not mentioned) for free hospital beds. One-tenth of the estate of James F. Hope also was left to Jefferson Hospital. The total value of the estate is said to exceed $100,000.

South Carolina.—The Medical College of the State of South Carolina, Charleston, by legislative enactment was made a state institution and also an appropriation of $10,000 was made. A campaign for additional funds for the medical school resulted in raising from the citizens of Charleston $76,000 in subscriptions in ten days' time.

Tennessee.—Vanderbilt University Medical Department has received a gift of $1,000,000 from Mr. Andrew Carnegie.

Wisconsin.—The University of Wisconsin secured an appropriation for $200,000 for a new medical or physics building, with a certainty that the College of Medicine will be better housed whichever building the money is used for.

Totals	4564	4093	3639	4444	17015

Note.—This table gives for each college, from which the information was obtainable, the number of students enrolled in each of the four classes. The colleges marked with an asterisk (*) either do not publish classified lists of their students in their announcements, or otherwise the information was not obtained. For these colleges the figures given in the fourth-year column show the number graduated. The College of Physicians and Surgeons of Boston reported a list of 181 "matriculants and applicants" which also included dental students. On fairly reliable information it is estimated that about 80 medical students were actually enrolled, or about 20 in each class. Nine colleges gave only the work of the first two years and two colleges, the University Medical College of Kansas City and the Ensworth Medical College, St. Joseph, Mo., gave only the work of the clinical years.

This table is very interesting in the light of the rapid trend toward higher entrance requirements. This table should be studied in connection with the lists of colleges on page 587 which have adopted higher entrance requirements. In every instance where the first year class shows a marked increase the medical college is one which has continued to hold to a four-year high school, or lower, entrance requirement, in face of the sweeping and voluntary movement by medical colleges generally toward the requirement of one or more years of liberal arts' college work for admission. The colleges having the most noticeable increases, given in the order they appear in the list, are the Bennett Medical College, Chicago; the Chicago College of Medicine and Surgery; Jenner Medical College, Chicago; University of Illinois College of Medicine; Tufts College Medical School, Boston; American Medical College, St. Louis; Long Island College Hospital, Brooklyn, and Jefferson Medical College, Philadelphia. On the other hand by examining this table the reader can pick out colleges which began last fall to enforce higher entrance standards. The Atlanta College of Physicians and Surgeons began a more rigid enforcement of the fourteen unit high school standard. Six colleges which began the requirement of one year of collegiate work are Howard University School of Medicine, Washington; Medical School of Maine, Portland; University of Michigan Homeopathic College, Ann Arbor; University and Bellevue Hospital Medical College, New York City; Baylor University College of Medicine, Dallas, and the University of Vermont, College of Medicine, Burlington. Two colleges which began the requirements of two years of college work, are Georgetown University School of Medicine, Washington, D. C., and Washington University School of Medicine, St. Louis. In this connection it is interesting to note on page 587 that thirteen state medical licensing boards have adopted higher standards of preliminary education, and that seven of them, Colorado, Indiana, Iowa, Kentucky, Minnesota, North Dakota and South Dakota, require as a minimum two years of collegiate work.

The five colleges having the largest enrollment are Jefferson Medical College, 680; Chicago College of Medicine and Surgery, 642; University of Illinois, College of Medicine, 535; Long Island College Hospital, 438, and Rush Medical College, 422.

SATURDAY, AUGUST 23, 1913

MEDICAL EDUCATION IN THE UNITED STATES

The tabulated statistics herewith presented (pages 569 to 598) are for the year ending June 30, 1913, and are based on signed reports received directly from the medical colleges or from other reliable sources. We take much pleasure in acknowledging here the courtesy and cooperation of the various officials of the medical colleges which have made the compilation of these complete statistics possible.

STATISTICS OF COLLEGES

Table 1 (pages 590 to 592) gives the colleges in session during 1912-13; the population of the city in which each college is located; the rating given to the college in the third classification of the Council on Medical Education; the number of students, men and women, registered during the year; the number of 1913 graduates, men and women; the number of graduates holding collegiate degrees; the number of teachers for each college; the number of weeks of actual work in the college year; the total fees for each year; the executive officer of the college and the dates of beginning and ending of the next session. The figures in heavy-faced type show the totals by states. Beginning on page 569 are given essential facts concerning all medical colleges, arranged by states.

NUMBER OF MEDICAL STUDENTS

The total number of medical students (matriculants) in the United States for the year ending June 30, 1913, excluding special students, was 17,015, a decrease of 2,771 below 1911, a decrease of 4,511 below 1910 and a decrease of 11,127 below 1904, when the highest number of students was enrolled. In fact, it is the lowest number since THE JOURNAL began compiling these statistics in 1900. Of the total number of students, 15,909 were in attendance at the so-called regular colleges, 850 at the homeopathic, and 256 at the eclectic colleges. The attendance at the regular colleges shows a decrease of 1,368 below that of last year and 2,505 below 1911. In the homeopathic colleges there was an increase of twenty-three above the attendance of 1912, but a decrease of forty below the total for 1911. The eclectic colleges show a decrease of fifty-two below 1912 and a decrease of 177 below 1911.

TABLE 4.—MEDICAL COLLEGE ATTENDANCE

Year.	Regular.	Homeo-pathic.	Eclectic.	Physio-Med.	Nonde-script.	Total.

1913..........	15,919	850	256	...	...	17,015

NUMBER OF MEDICAL GRADUATES

The total number of graduates for the year ending June 30, 1913, was 3,981, a decrease of 502 below 1912, a decrease of 292 below 1911, and a decrease of 459 below 1910. The total this year is 1,766 less than in 1904, when the largest number were graduated. The percentage of graduates to matriculants was 23.4 this year, as compared with 24.7 in 1912 and 21.6 in 1911.

TABLE 5.—MEDICAL COLLEGE GRADUATES

Year.	Regular.	Homeo-pathic.	Eclectic.	Physio-Med.	Nonde-script.	Total.
1880..........	2,673	380	188	..	..	3,241
1890..........	3,853	380	221	..	..	4,454
1900..........	4,715	413	86	..	..	5,214
1901..........	4,879	387	148	18	12	5,444

1903..........	5,088	420	149	24	17	5,698
1904..........	5,190	371	146	20	20	5,747
1905..........	5,126	276	153	22	23	5,600
1906..........	4,811	286	186	22	29	5,364
1907..........	4,591	225	121	11	32	4,980
1908..........	4,370	215	116	12	28	4,741
1909..........	4,163	209	84	15	44	4,515
1910..........	4,113	183	114	16	14	4,440
1911..........	4,006	152	110	5	..	4,273
1912..........	4,206	185	92	..	..	4,483
1913..........	3,679	209	93	..	..	3,981

The number of graduates from the regular colleges was 3,679, or 527 less than last year, 327 less than in 1911 and 434 less than in 1910. From the homeopathic colleges there were 209 graduates, or twenty-four more than in 1912, fifty-seven more than in 1911 and the same number as in 1909. The eclectic colleges graduated ninety-three, or one more than last year, but seventeen less than in 1911 and twenty-one less than in 1910. Of the 3,981 medical graduates, 753, or 18.9 per cent., were reported to hold also degrees in arts or science, as compared with 17 per cent. last year, 16.5 per cent. in 1911 and 15.3 per cent. in 1910. Of the 3,679 regular school graduates, 732, or about 20 per cent., were reported to have baccalaureate degrees, while of the homeopathic graduates, twenty, or 9.5 per cent., were so reported, and of the eclectic graduates only one (less than 1 per cent.) was reported as holding a degree from a college of liberal arts. As will be noted by referring to Table 12, of the 753 graduates holding baccalaureate degrees, 139—the largest number—came from Illinois colleges, followed by 99 from New York, 80 from Maryland, 73 from Pennsylvania and 60 from Massachusetts. It is expected that in future the percentage of graduates holding collegiate degrees will increase, since a larger number of medical schools are requiring college work for admission.

WOMEN IN MEDICINE

During the past year there were 640 women studying medicine, or thirty-nine less than last year, a decrease of forty below 1911 and a decrease of 367 below 1910. The percentage of all medical students was 3.8, as compared with 3.2 last year. There were 154 women graduates this year, or 3.8 per cent. of all graduates. There has been a very marked decrease in the number of women in medicine since 1910, when there were 907 women students and 157 graduates, and in 1909, when there were 921 women students and 162 graduates. Of all the women matriculants, 138 (21.6 per cent.) were in attendance at the two medical colleges for women, as compared with 143 (21.1 per cent.) in 1912, 134 (19.7 per cent.) in 1911 and 155 (17.1 per cent.) in 1910. The remaining 502 (78.4 per cent.) were matriculated in the fifty-five coeducational colleges. From the two women's colleges, there were thirty-three, or 21.4 per cent., of all women graduates, while 121, or 78.6 per cent., secured their degrees from coeducational colleges.

NUMBER OF COLLEGES.

Heretofore no exact data were available on which absolute statements could be made regarding the number of medical schools existing in any certain year. The Council on Medical Education has succeeded in collecting reliable data regarding all medical schools from which it was possible to construct the chart appearing on pages 578 to 581 of this issue. By means of this chart the actual number of schools existing in any one year can be positively stated, where heretofore only estimates were possible. Table 7, therefore, allowing of comparisons between the number of colleges existing in recent years, has been revised in accordance with this life chart.

Since June 30, 1912, fourteen colleges (mentioned on page 596) have either suspended or have merged with others, and two new colleges have been organized, leaving 106 medical colleges still existing. The number of colleges is the smallest number since 1880. It was about that time that the movement toward establishing medical colleges for profit became most marked, and the rapid increase in the number of colleges has been paralleled only by the rapid decrease since 1904. There has been a net decrease of *fifty-six colleges since 1906*, when there were 162 colleges. Seventy-nine colleges have been closed by merger or otherwise since 1904, but in the same time twenty-three new colleges were organized, leaving 106 medical colleges which still exist. The regular colleges number *ninety-one*, a decrease of ten since last year. The homeopathic colleges number ten, a decrease of one since last year and the eclectic colleges number five, a decrease of one since last year.

TABLE 7.—Medical Colleges
Revised according to Life Chart, p. 578

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med.	Nondescript.	Total.

1913.........	91	10	5	..	..	106

FEWER BUT BETTER COLLEGES

Of the seventy-nine medical colleges which have ceased to exist since 1904, forty-seven were closed by merger and thirty-two became extinct. It is noteworthy that this rapid diminution in the number of colleges began following the creation of the Council on Medical Education in 1905, and became more marked following the Council's first classification of medical colleges issued in

TABLE 8.—Colleges Closed Since 1904

Totals..	22	1	19	2	6	29	47	32	79

* Based on the classifications of medical colleges prepared by the Council on Medical Education.

1907. The largest numbers closing in single years were thirteen in 1910, when the Council's second classification was published, and fourteen last year, when the third classification was made public.

It is interesting to note also that most of the closures of medical schools in Classes A and B were by merger, whereas all but three of the medical schools which became extinct had been rated in Class C.

While the total number of colleges is growing smaller, however, and approaching more nearly the normal supply for this country, it is encouraging to note that the number of high-grade, stronger medical colleges is constantly increasing. In 1904 only four medical colleges were requiring any preliminary education in advance of the usual high-school education; now there are fifty-three[1] requiring one or more years of advance college work and twenty-eight others which begin the higher requirement next year. The colleges have been remarkably improved also in regard to buildings, new laboratories, better equipment, larger hospital facilities and—most important—more and better full-time, salaried instructors.

FURTHER MERGERS NEEDED

Only nineteen cities still exist which have two or more medical schools, and in eight of these mergers are scarcely possible, owing to the fact that the schools differ as to sect or race, leaving eleven cities where mergers are still possible. These cities and the number of colleges in each between which mergers are possible, are as follows: Chicago, 6; New York, 5; Baltimore, 4; St. Louis, 4; Boston, 3; San Francisco, 3; Los Angeles, 2; Washington, 2; Dallas, 2, and Omaha, 2. In 1904 there were twenty-four cities having each from two to eight regular medical schools. More mergers should be brought about.

TABLE 9.—CITIES HAVING TWO OR MORE MEDICAL COLLEGES

* One school for the colored race.

The most famous medical centers in Europe—for example, Berlin, Paris, Vienna—have but one large medical school each, which makes systematic use of all the clinical facilities of its respective city. There is no valid reason why this country should not have equally famous medical centers, but the highest development is prevented by the existence of two or more competing medical schools. For the further improvement not only of undergraduate but also of postgraduate medical instruction in this country, there should be other mergers in the eleven cities named.

LENGTH OF TERMS

The length of term of each college fluctuates somewhat from year to year, but on the whole, during the last twelve years there has been a decided lengthening of college terms. This has reference to the weeks of actual work exclusive of holidays. Only three colleges this year reported sessions shorter than twenty-nine weeks, whereas in 1901, one hundred colleges reported sessions of from twenty-three to twenty-eight weeks. Five colleges claim courses of twenty-nine or thirty weeks of actual work, twenty-nine claim courses of thirty-one or thirty-two weeks, and forty-one, the largest number, claim courses of from thirty-three to thirty-four weeks. Of the 106 colleges now existing, ninety-seven, or 91.5 per cent., now claim to require from thirty-one to thirty-six weeks of actual work, exclusive of holidays, as compared with 85 per cent. in 1912, 76 per cent. in 1910, 42 per cent. in 1904 and only 30 per cent in 1901. The one college claiming a course longer than thirty-six weeks is a night school, but it would require twelve or fourteen years of the usual night-school study, however, to obtain the equivalent of four years of thirty-two weeks each in one of the better day colleges.

TUITION AND OTHER FEES

Special attention is called in Table 1 to the total amount charged by the various colleges for tuition, matriculation, laboratory and graduation fees per annum for each student. In Table 11 the 106 remaining colleges have been grouped according to the amount of fees charged and according to their classification by the Council on Medical Education in Classes A, B and C. Twenty-three colleges charge fees of $100 or less per year, sixty-five between $100 and $175, and eighteen charge above $175. Of the twenty-three colleges charging $100 or less, twelve, or over half, were listed among Class A (acceptable) colleges[2] by the Council on Medical Education, five were among Class B colleges, and only six of them are found among the Class C colleges. Among the ten Class A colleges having these low fees are the schools of medicine of the state universities of Colorado, Iowa, Mississippi, Missouri, North Dakota, South Dakota, Texas and Utah. On the other hand sixteen colleges listed by the Council in Class C charge fees of from $100 to $175 per year for each student. As shown on page 587 diplomas from Class C colleges are reported as not recognized by twenty-four state licensing boards. It is a question, therefore, why a student should spend his time and money in a low-grade college the diplomas of which are not recognized in many states, when in the same time and with even less money he can attend one of the best equipped colleges the diplomas of which are recognized in all states? Although fifty colleges listed in Class A charge fees ranging from $150 to $275 per year for each student, the actual expense for teaching that student in these colleges amounts to from two, or three to several times those sums.

* Based on the latest classification of medical colleges prepared by the Council on Medical Education.

COLLEGES, STUDENTS AND GRADUATES BY STATES

Illinois has heretofore had the largest number of medical colleges, but now the first place is held by New York, where there are ten colleges. Missouri and California each have eight and Illinois and Pennsylvania each have seven colleges. Illinois still has the largest number of students enrolled, having 2,496 matriculants last session, followed by New York with 2,204. Pennsylvania with 1,700, Tennessee with 1,213 and Maryland with 1,171. In regard to the graduates the same relative position obtains.

Table 13 shows the colleges existing last session and their students and graduates grouped according to their rank in the third classification of the Council on Medical Education. As will be noted, there were sixty-eight colleges in Classes A+ and A and 25 each in Classes B and C. It is encouraging to note that over 65 per cent. of all students are enrolled in the 56 per cent. of colleges which are in Class A+ and A and that these colleges turn out over 63 per cent. of all graduates. At the other extreme only 10.2 per cent. of all students and 9.8 per cent. of all graduates are from the 21.2 per cent. of colleges rated in Class C.

HOME STATES OF MEDICAL STUDENTS

Table 2, on pages 594 to 597, shows from what states the students come who were in attendance at each medical college during the session of 1912-13. The influence of the proximity of the medical school is seen in the fact that states having medical colleges contribute more students in proportion to the population than those which have no colleges. This is shown by the dark zone of figures running diagonally down the page. A comparison of this table with the large tables based in state board examinations,[3] which show the distribution of the alumni of each college, is interesting. The college which has widely distributed alumni usually has a student body from an equally large number of states.

The state furnishing the largest number of students this year was New York, with 2,098. Pennsylvania contributed 1,375 and Illinois 1,314. The next states, in the order of the number of students contributed are: Ohio, 795; Massachusetts, 680; Texas, 594; Missouri,

---

3. The Journal A. M. A., May 24, 1913, p 1624.

562, and Tennessee, 436. Four states had less than twenty each, these being Arizona fourteen; Wyoming, ten; New Mexico, eight, and Nevada, four. There were eighty-nine students from Hawaii, Porto Rico and the Philippine Islands, and 562 students from foreign countries.

STUDENTS ENROLLED BY CLASSES

In Table 3, on page 598, the students enrolled in each college are shown by classes. This permits one to see whether the attendance at each college is increasing or decreasing. The total attendance for the first year in all colleges is larger than that of the second year by 471. More interesting, however, is the study of this table in the light of higher entrance requirements which have been adopted during the last two or three years by a large number of colleges.[4] The effects of these higher requirements are shown in the figures in two ways: smaller enrollments for the colleges which have adopted the higher requirements and larger enrollments for the colleges which have retained the lower requirements. The benefit in larger classes for the "stand-pat" colleges can be only temporary, however, so decided is the trend for the higher standards. Already thirteen state licensing boards have gone on record for the higher requirements and others are contemplating similar action. The House of Delegates of the American Medical Association in June, 1912, adopted a report instructing the Council on Medical Education to omit from the acceptable list any medical college which after Jan. 1, 1914, does not require for admission in addition to the four-year high-school education, at least one year of higher preliminary work, including courses of college grade in physics, chemistry and biology. The Association of American Medical Colleges has adopted a similar requirement. The medical profession in the United States, therefore, has gone on record for entrance qualifications which bring medical education in this country more nearly on a par with the requirements of other countries.

The next great wave of improvement, and which has already begun, is the establishing of closer relationships between hospitals and medical schools, whereby each of the hospitals will have on its attending staff the most skilled physicians who are engaged in teaching and research, and the medical school will possess a teaching hospital where students may see and study patients at the bedside. This closer relationship is a direct acknowledgment on the part of the hospital that the medical school has improved to such an extent that it is a real honor and a benefit to have a closer relationship with it. This closer relationship undoubtedly means that the hospitals will be conducted along more modern lines; it means that medical students will be given a better training in the examination and care of patients and, last but not least, it means that the public will in future be supplied with better qualified physicians.

---

[4] See lists on page 587.

HASTY GENERALIZATION IN THERAPY

The search for "specifics" for the various ailments that beset mankind has become so keen in recent years, partly because of the striking success in a few familiar instances, and the competition among drug manufacturers to meet these obvious wants has become so brisk, that there is at present an overshadowing danger from a sort of reckless medication which may in the end react unfavorably on the advance of chemotherapy. A few experiments are carried out on animals, often without adequate controls; the observer is inspired with a possibility of the therapeutic application of his hasty findings; the clinic and the patient are drawn into requisition; the healing propaganda is launched; the manufacturer helps it on its way; and not infrequently the nostrum vender reaps an unsuspected harvest in the new land of promised health. Then comes the awakening. The premises are found to be wrong, the experimental evidence inadequate, the clinical observations conflicting or uncertain, and the vaunted cures are dispelled.

We are impelled to illustrate this by reference to a recent instance. There are comparatively few well-founded examples of any profound changes in the chemical composition of the fundamental tissues incident to disease. Many of the perversions of physiologic behavior are functional rather than organic in character. It has long been believed that some of the diseases of the central nervous system, particularly those in which anatomic lesions or alterations are known to occur, are attended by changes in the chemical make-up of the tissue. Owing to the technical difficulties in the analysis of nervous matter, the proof has not easily been furnished. Not long ago Carbone and Pighini[1] asserted that in the brain of individuals dying of progressive paralysis the proportion of one of the brain phosphatids, cephalin, is markedly reduced. This announcement promptly awakened the hope of a corresponding therapy of nervous disease.

Several years ago Franchini[2] attempted to "enrich" tissues in lecithin by the administration of lecithin. He employed the product prepared from egg-yolk and believed that he could actually demonstrate a deposition of this lipoid in the liver. In the case of the brain, however, no evidence of any increase in phosphatids could be discovered as the result of furnishing egg lecithin to the body. Fränkel contends that the human brain does not contain the ordinary lecithin, but a phosphatid of different type—a triaminodiphosphatid which he has named "sahidin." In view of the differences in the results of experimental feeding suggested by the specific peculiarities of the species, Salkowski,[3] the well-known pathologic chemist of Berlin, has been impelled to repeat the experiments on phosphatid administration, using the closely related cephalin in place of lecithin.

---

[1] Carbone and Pighini: Biochem. Ztschr., 1912, xlvi, 451.

[2] Franchini. Biochem. Ztschr., 1907, vi, 211.

[3] Salkowski, E.: Ist es möglich, den Gehalt des Gehirns an Phosphatiden zu steigern? Biochem. Ztschr., 1913, li, 407.

The outcome of his trials with animals has been that cephalin—already an article of commerce—is well tolerated and apparently readily absorbed. In contrast with what Franchini reported for lecithin, cephalin was not deposited in the liver, but was said to become stored in the brain. When one examines Salkowski's data critically, however, *they bring little conviction*. The actual increment of phosphatid found by him—and that in only a very limited number of experiments—is so small as almost to fall within the limits of experimental error in such kinds of investigation. Salkowski argues that in a tissue which resists alterations in its chemical make-up as stubbornly as does the brain, the increment of even 5 per cent. of any component—the figure recorded for his cephalin trials—is *noteworthy*. He therefore regards it as probable that cephalin can be introduced into the nervous tissue in this way and suggests that his experiments justify the attempt to employ the otherwise harmless cephalin in progressive paralysis and other cerebral affections.

Despite Salkowski's apologies for the limited number of experiments on which he has based his conclusions, one can already foretell the probable outcome of such a recommendation by a well-known medical investigator. Lecithin- and cephalin-therapy will receive an impetus as yet quite unwarranted by the facts at hand. Skilful advertising will do even more. It is not that we object to the therapeutic trial of promising procedures or chemical compounds, for that is the way in which progress is initiated. But in these days of abundant facility for research one may reasonably expect that the purely empirical mode of clinical investigation will be supplemented, if not replaced, by a scheme of observation based on encouraging evidence when such is procurable. It is, of course, true that exact science grows slowly and that painstaking preliminary experiments are laborious and costly. Yet it is precisely the unsatisfactory outcome of haphazard trials, the unfortunate *exploitation* of inadequately controlled panaceas, the failure of ill-timed and unwarranted medication, that have perhaps done more than anything else to cast an undeserved stigma on the utility of much modern therapeutic research. In the interest of this legitimate and important field of medical investigation, productive of helpful results when conducted on a rational basis, this protest against overhasty generalizations from "preliminary" investigations is made.

COMPARISON OF POLYNEURITIS OF FOWLS WITH HUMAN BERIBERI

It would seem that there can be no doubt that beriberi in man is the result of a too nearly exclusive diet of polished rice, or of other foods lacking in what we may for the present, term a neuritis-preventing substance; such at least are the conclusions justified by the extensive studies of Fraser and Stanton[1] and of Strong and Crowell.[2] It has likewise been proved that polyneuritis of fowls—so-called polyneuritis gallinarum—can be induced by a similar diet. The cause of the two diseases is therefore the same, and abundantly justifies the use of the experimental animal in the search for curative or preventive measures to be applied to the human situation.

In this way we have learned that both meat and potatoes contain a certain, but relatively small, amount of the neuritis-preventing substance; and the immunity from beriberi of those races whose main articles of diet are meat and potato is explained. We have learned, further, that ordinary white bread is quite lacking in antineuritic substance; and thereby light is thrown on the appearance of beriberi on Norwegian sailing ships about 1894, when wheat bread was substituted for rye bread in the dietary. A similar result was reported by Little[3] in respect to the native population of Labrador and Newfoundland which lives almost exclusively on white wheat flour at certain seasons. By experimental methods it has further been shown that probably most leguminous seeds—peas, beans, peanuts, etc.—will be efficacious as an antineuritic adjuvant to restricted dietaries of bread or rice.

Despite the useful comparisons which have been made and the analogies discovered, it now appears from the investigations of the U. S. Army Board for the Study of Tropical Diseases as They Exist in the Philippine Islands[4] that the symptomatology and pathology of polyneuritis gallinarum cannot be regarded as identical with that of beriberi in man. As the Manila investigators, Vedder and Clark, note, there is more similarity than difference between the two diseases. They have never observed any edema in fowls at all comparable to wet beriberi in man, however, and while there are undoubtedly slight changes in the hearts of fowls suffering from polyneuritis, there is none of the hypertrophy which is such a characteristic finding in human beriberi. With respect to the fowls it also appears that the disease is not simply a peripheral neuritis as has generally been supposed; on the contrary, the entire nervous system appears to be affected. The symptoms of the disease in fowls, Vedder and Clark maintain, are not chiefly referable to degeneration of the peripheral nerves. Degeneration occurs before symptoms arise; advanced degeneration may be present accompanied by no symptoms at all; and degeneration of the nerves remains after recovery has occurred.

THE IRREDUCIBLE MINIMUM OF KIDNEY SUBSTANCE

The liberal surplus of renal tissue which the body possesses for the purposes of urinary secretion is sufficiently emphasized by the absence of any pathologic systemic upsets when an entire kidney is removed, as occasionally happens in surgical experience. One intact remaining kidney can adequately perform the functions of excretion which the metabolism calls for. At what point the limit of safety is reached, that is, how much kidney substance is indispensable for the routine requirements of the organism, is primarily a question for experimental solution. One method has consisted in excising segments of the organ and thus by gradual reduction of the kidney substance determining what is the irreducible minimum of the latter compatible with the continuance of health. Those who have proceeded in this way have placed the limit at not less than one quarter of the renal tissue. Pearce, whose observations are perhaps the most careful of all those based on this method of excision, concluded that the removal of larger amounts, and sometimes of three quarters of the substance, leads to the metabolism condition of starvation.[1] The metabolism in excessive kidney reduction is that of inanition dependent on gastro-intestinal disturbances presumably due to faulty chemical correlation. Apparently toxic substances are eliminated into the intestine. Bradford's reduction experiments even led him so far as to suggest that the kidneys have an influence on general metabolism; for he observed conditions which appeared to him to be due, not to retention of products of normal metabolism, but to an increased tissue disintegration affecting especially the muscles. Subsequent researches have made it appear probable, however, that mere reduction of kidney substance, even to a minimum compatible with life, does not lead to disturbances of metabolic function capable of being utilized in the explanation of uremia.

Nature's method of bringing about a pathologic decrease in the amount of functioning renal tissue is usually far less sudden and certainly less severe than any process of instantaneous surgical excision. The phenomena of disease are more closely imitated by the plan of inducing necrosis by ligation of branches of the renal arteries.[2] When this is carried out, as it has been by Dr. Pilcher[3] in Cleveland, the functional efficiency of the kidney appears in even more favorable light than heretofore. As might be anticipated, ligation of one branch of both renal arteries, that is, approximately half of the blood-supply, does not cause any noticeable disturbance in renal performance. The urine remains practically normal. Shutting off three fourths of the arterial supply results in marked temporary prostration, anorexia and loss of weight, with nitrogen output much greater than the intake. The animals gradually recover, however. On the apparently justified assumption that the ligated areas take no part in urine formation, it is permissible to conclude that one fourth of the kidney is able to secrete urine almost as effectively as the entire kidney area. The urine was practically normal: there was an absence of protein and casts. Cardiac hypertrophy did not occur.

The theory that the kidney furnishes an internal secretion having an important influence on general metabolism has been exploited repeatedly since it was first brought to general notice by Brown-Séquard.[4] There is little to substantiate it at present. Certainly if such a function exists it is not noticeably disturbed by events which exclude the physiologic activity of 75 per cent. of the kidney substance.

Current Comment

CHEMICAL CHANGES PRODUCED IN COW'S MILK BY PASTEURIZATION

It has been stated frequently that pasteurizing milk changes its chemical composition and renders it less digestible and less suitable for infants. The changes which are said to take place are chiefly the precipitation of soluble phosphates, which change produces defective nutrition, and the altered constitution of casein and lactalbumin, which renders pasteurized milk inferior as food. These objections originated at the time when high temperatures were employed for pasteurization, and in the absence of reliable investigations were tacitly applied to modern pasteurization at low temperatures. Rupp[1] publishes a series of experiments to determine the following points: (1) the changes in soluble phosphates of lime and magnesia; (2) the extent of change in the protein, and (3) the change in acidity produced by pasteurization of milk at various temperatures. Pasteurizing milk at 155 F. for thirty minutes did not change the amount of soluble phosphate of lime beyond the limits of experimental error, and the phosphate of magnesia remained unchanged. The albumin content was tested in raw milk and in milk pasteurized at various temperatures for thirty minutes. At 145 F. no albumin coagulated; at 150 F. 5.71 per cent. were insoluble, and at 155 and 160 F., 12.76 and 30.87 per cent., respectively, were insoluble. The coagulability of casein with rennin was tested in similar fashion. When the pasteurization temperature was 131, 140 and 149 F., the casein coagulated more rapidly than in raw milk. Retardation of rennin coagulation commenced at 158. Coagulation consumed twice the time as compared with raw milk at 167. The acidity of the milk was slightly reduced after pasteurization. Rupp concludes that milk pasteurized by the holding process at 145 F. for thirty minutes suffers no appreciable chemical change. The soluble phosphates of lime and magnesia do not become insoluble at 155. The lactalbumin does not coagulate at 145, but begins to become insoluble at 150. The time required for coagulation of casein is slightly reduced in milk pasteurized at temperatures up to 149 F. The results are especially interesting as they dispose of another prejudice against the pasteurization of milk.

SUICIDE WITH BICHLORID OF MERCURY

Some weeks ago, considerable publicity was given a case of accidental poisoning from bichlorid of mercury tablets. The case was so "featured" as to lead the public to infer that corrosive sublimate poisoning was not only a sure but also a painless route to the other world. Since this accident, the papers have chronicled, almost daily, cases of suicide in which bichlorid of mercury was the drug used. There is no doubt that many unstable persons who, in fits of depression contemplate suicide, are restrained from taking the fatal step by the dread of the unknown agony they may suffer in committing it. To such, the knowledge of a sure and painless method of death removes the only restraining influence left. It is fitting, then, that the public should be acquainted with the fact that there are few modes of suicide more painful and in which the agony is longer drawn out than that due to the taking of bichlorid of mercury. If this fact were given the same publicity that was accorded the case of accidental poisoning, there is little doubt that the corrosive sublimate method of self-destruction would cease to be the fatal fad it has recently become.

THE ADVERTISING OF LOW-GRADE MEDICAL COLLEGES

There are a number of seriously low-grade colleges which depend for their existence on the ready acceptance of their advertisements by lay newspapers and periodicals and by medical journals. For example, the Chicago Hospital College of Medicine, an "afternoon and evening college," regarding the origin of which comment has previously been made,[1] apparently has had no difficulty in placing its advertisements even though it is reported by the Illinois State Board of Health as "not in good standing" and its diplomas, therefore, do not make the holders eligible to practice medicine in Illinois or the majority of other states. Another example is the Jenner Medical College, whose advertisement has appeared regularly in several Chicago newspapers and in some of the popular periodicals. The advertisement of the latter college includes the statement, "Fully recognized by the Illinois and other state boards of health" notwithstanding the fact that official statements from twenty-nine state licensing boards report this college as not fully recognized. Through shrewd advertisements such institutions as these are enabled to prey on public ignorance, and to profit directly or indirectly by taking the hard-earned money of the "poor boy" whom some of them profess to serve. If there were a dearth of thoroughly equipped medical colleges, or if there were a lack of opportunity for worthy students who are poor in purse to secure a medical education, then there might be some justification for upholding these inferior colleges. But such is not the case. This country still has fully one-third of the world's supply of medical colleges, and among these are now many which in standards, teachers, equipment and clinical facilities compare favorably with any abroad. Furthermore, in several of these thoroughly equipped colleges the student can secure an excellent training in the same time and with even less money than he is required to pay in low-grade institutions. Again, the diploma from the better school entitles the graduate to practice medicine in any state of his choice, while a diploma from the low-grade college is now not recognized in most of the states. A glance at the lists of students enrolled in these inferior colleges shows that a large proportion are foreigners who, doubtless having in mind the unquestionably high standards of medical schools abroad and being unacquainted with the amazing diversity of standards among the medical schools in this country, become an easy prey to the self-laudatory if not actually misleading advertisements of these inferior colleges. It is certainly morally wrong if not an actual crime for a medical institution to entice students to enter a profession for which they may not be fitted educationally or otherwise; even more so if that institution is without adequate equipment. It is doubly wrong to take the hard-earned money of the student of limited means and allow him to spend several years of his life in obtaining a degree which when secured does not qualify him for a license to practice in the majority of the states. This action does the student an injury which may seriously affect his entire life, and the practice is aided and abetted by the newspapers and magazines which are willing to carry the advertisements of such schools. We cannot believe that any self-respecting newspaper editor would accept such advertisements if he were acquainted with the facts. It is about time that some thought be given to the injury to the students who are made the prey of such institutions.

Medical News

ALABAMA

City Hospital for Montgomery.—The Ladies' Infirmary Association of Montgomery has offered to contribute $30,000 toward the erection of a city hospital, asking the city in consideration thereof to donate $2,500 annually toward the maintenance fund.

CALIFORNIA

Personal.—Dr. A. P. O'Brien has been appointed police surgeon of San Francisco, vice Dr. Mahoney, deceased.

State Hospitals Organize.—The executive heads of the hospitals of California met in Los Angeles, July 31, and formed the organization of California hospitals to foster the improvement of hospital management and to promote friendly intercourse among the staffs of the component hospitals. Dr. H. P. Barton was elected president and Dr. D. Gochenaur, San Diego, vice-president.

ILLINOIS

The Fight Against Tuberculosis.—Cass County Association for the Prevention of Tuberculosis was organized at Virginia, July 30, with Drs. Albert R. Lyles, Virginia; John G. Franken, Chandlerville; Jos. M. Swope, Arenzville, and Jas. A. Glenn, Ashland, vice-presidents.——Bids for eight cottages for the tuberculosis department of Oak Forest Infirmary were received by the Cook County Board of Commissioners August 4. The bids varied from $112,800 to $142,984.

---

[1] Another Joint-Stock Medical College for Chicago? editorial, The Journal A. M. A., Jan. 13, 1912, p. 122.

Hospital Notes.—At a meeting of the board of trustees of the Watseka Hospital, July 30, A. F. Goodyear was elected president of the board and it was voted to take up the deed of the Larson property on which the hospital is to be erected. A committee was appointed to investigate building plans and have the construction of the hospital carried on as rapidly as possible.——Plans have been executed and contracts are being awarded for a new contagious hospital to be built in Evanston by James A. Patten. Mr. Patten offered to build such a hospital if $100,000 should be subscribed by citizens of the town as an endowment fund. The building is to be four stories in height, the three upper stories being devoted to hospital wards.

Chicago

Coroner's Laboratory Opened.—An analytical laboratory for the coroner's office has been opened in the County Building and work has been commenced by the coroner's chemist, Dr. William D. McNally.

Jury of Women.—The first jury of women ever impanelled in Cook County passed on insane cases at the Detention Hospital Court, August 7. Dr. Clara P. Seippel, assistant city physician, was foreman of the jury and Dr. Anna Dwyer a member.

INDIANA

Hospital Notes.—The Board of State Charities, at its meeting July 29, authorized the erection of the building of a new county infirmary for Fayette County.——The new Elkhart General Hospital, recently completed at a cost of $80,000, was opened for public inspection, July 26-27, and for the reception of patients, July 29. The building is three stories with accommodation for forty-eight patients.——Members of the Masonic Fraternity of Fort Wayne have started a movement for organizing a non-sectarian hospital in that city. The proposition contemplates taking over Hope Hospital, rebuilding it and providing it with an entirely new equipment.——Frances Willard Hospital and Training School has been incorporated at Hammond with a capital stock of $60,000.——The cornerstone of the new St. Francis Hospital, Beech Grove, Indianapolis, was laid by Bishop Chartand, July 16. The hospital is to be conducted by the Sisters of St. Francis, will cost about $200,000 and will accommodate 200 patients.

Personal.—Dr. T. L. Eads of Michigan City was robbed August 9 of a gold watch and $21,000 in mortgage notes.——Dr. G. W. Buckner, a colored physician of Evansville, has been appointed United States Minister to Liberia.——The following physicians of Indianapolis spent the summer abroad in travel and attending the International Medical Congress: Dr. J. F. Barnhill, Dr. W. F. Clevenger, Dr. David Ross, Dr. John Oliver, Dr. H. O. Pantzer, and Dr. A. C. Kimberlin.——Dr. Thomas Kennedy, ex-president of the Indiana State Medical Society, Dr. J. H. Eberwain, and Dr. Charles R. Sowder, who have been seriously ill, have recovered their health.——Dr. B. B. Pettijohn, Indianapolis, after taking examination, has been commissioned in the Medical Reserve Corps of the United States Army.——Dr. Frank W. Foxworthy, Indianapolis, chairman of the program committee, attended the American Life Convention which met in annual session at St. Paul, August 19 to 22.——Dr. C. R. Strickland, Indianapolis; Dr. J. C. Sexton, Rushville, accompanied the Indiana auto manufacturers on their coast trip as staff surgeons.

KENTUCKY

New Milk Station Opened.—A new milk station was opened by the Louisville Babies' Milk Fund Association at the Whittier School at Thirteenth and Maple Streets. Clinics are held each Wednesday afternoon and a trained nurse is on duty between 2 and 3.

Tuberculosis Commission to Employ Nurses.—Four district nurses will be employed by the State Tuberculosis Commission to visit communities which will pay the living expenses of the nurses and to introduce a system of district nursing. Three counties have requested already that nurses be sent there.

MARYLAND

Public Welfare Exhibit.—The public health exhibit of the Medical and Chirurgical Faculty opened for a week on August 11 at the Young Men's Christian Association Building in Frederick. It includes alcohol, tuberculosis, infant mortality, and social and municipal sanitation.

Plans for Psychopathic Ward.—Plans for the psychopathic department to be established at the Springfield Hospital for the Insane were submitted at a meeting of the board of directors, July 30. The new building is to cost about $80 000 and the expense will be met by a bond issue recently authorized by the legislature. It will be built in the form of a cross and will be located between the men's and women's buildings.

Baltimore

Personal.—The following sailed for Bremen, August 12: Drs. J. L. Hooper and Robert Hoffmann of Baltimore, and Drs. Walter Fewkes and John A. Whaling of Washington.——Dr. A. L. Fahrsenfeld has been appointed medical examiner of schools, vice Dr. I. R. Page.

Water Treatment to Prevent Typhoid.—The health authorities are using 3,000 pounds of hypochlorite of lime daily with the view of purifying the drinking water and preventing the prevalence of typhoid fever. A report shows that 99 per cent. of the bacteria in the water last year were killed by the hypochlorite.

MICHIGAN

Building for Physicians.—S. S. Kresge is erecting an eighteen-story building at Park Street and Adams Avenue, Detroit, to cost about $700,000. Fifteen of the eighteen stories of this building are to be devoted to physicians' offices, and the building will be known as the Kresge Medical Building.

Hospital Notes.—St. Mary's Hospital, Detroit, has announced that it can receive no insane persons who are city charges, because of the crowded condition of the institution.——The new service building of Harper Hospital, Detroit, was opened August 4. The building is the center of the unit arranged for the hospital, 147x48 feet, and two stories in height.——The second floor of the new Hudson memorial Hospital is ready to receive patients and will accommodate twenty-two patients. The building when completed will be six stories in height and will accommodate one hundred and fifty patients.——A resolution was endorsed July 29 in the Detroit City Council empowering the Board of Poor Commissioners to acquire sufficient land on which to erect a hospital for the care of the sick poor of the city. The resolution was referred to the committee on health and city hospitals.

MINNESOTA

Plea for Sanatorium.—Drs. J. A. Gates, Kenyon, and M. W. Smith, Red Wing, made pleas before the county commissioners of Goodhue County for an appropriation of $15,000 for the establishment of a tuberculosis sanatorium for Goodhue County.

Sanatorium Notes.—Clay and Becker Counties have arranged to make a joint appropriation of $15,000, which, with a state appropriation of a like amount, will be sufficient for the construction of a new tuberculosis sanatorium with a capacity of thirty patients.——Otter Tail County has completed a sanatorium for tuberculosis at a cost of $40,000 with a sixty acre farm of which forty acres are under cultivation.——It has been decided that Duluth will not attempt any legal opposition to the Mercedes Sanatorium for Incurable Consumptives which Mrs. Julia Wood is planning to start.——The physicians of Goodhue County have launched a publicity campaign for the establishment of a county sanatorium in accordance with the recent act of the legislature.

NEW YORK

Personal.—Dr. William H. Jennings of Wellsville and Dr. J. William White of Fonda have sailed for Europe.

Death of Instrument Manufacturer.—J. M. Taylor, president of the Taylor Instrument Companies of Rochester, N. Y., *died* July 31.

New York City

Personal.—Dr. and Mrs. John P. Campbell, Dr. and Mrs. J. Clarence Sharp, Dr. Thomas R. Killilea and Dr. Francis E. Butler have sailed for Europe.

Cocain Users Sentenced.—Nine persons arrested in a raid recently have been sentenced to terms of imprisonment ranging from one to three months for using cocain. Of these six were women and three men. Ten other persons arrested in the same raid were taken to the Court of Special Sessions on the charge of selling cocain. This raid was a part of the campaign against cocain instituted some time ago by Rev. J. B. Curry of St. James Church.

Antitoxin Supplied Free of Charge.—The Health Department has sent a notice to physicians in Manhattan stating that it is believed that the death-rate from diphtheria can be reduced by the administration of 5,000 units of antitoxin on the first day of the disease. To further this end the department announces that beginning September 1 it will, whenever necessary, between the hours of 9 in the morning and 5 in the afternoon, deliver free of charge to any address in Manhattan antitoxin for the treatment of diphtheria.

The Infant Mortality-Rate.—The Babies' Welfare Association makes itself responsible for the statement that fewer babies in proportion to the population have died in New York City during the past six months than in any other important city in the United States. There were 100 fewer deaths of infants under 1 year of age than during the same period of 1912. Chicago, Philadelphia and Buffalo show a higher death-rate for the first six months of 1913 than for the corresponding period of 1912. The Welfare Committee think that the extreme heat of the present summer has affected the rate in this city unfavorably, especially in the more crowded sections, as might be expected.

Health Department Issues New Publication.—On the first of August the Department of Health sent out its first issue of a periodical for the information of employees of the department called "Staff News." This bulletin will be the official medium of communication of general orders from the board of commissioner, and of instructions issued by the heads of bureaus and divisions. It is hoped to expand this publication and to make it interesting and valuable to employees of the department who now number 3,036 and it is believed that it will be effective in developing a feeling of community of interest among employees and thus improve the service.

Reduction in Death Rate a Campaign Issue.—One of the main arguments of the fusionists for a continuation of anti-Tammany rule is that during the present city administration the infant death rate has been cut from 134 per 1,000 in 1910 to 120 per 1,000 in 1911 and a still further reduction in 1912. They lay great stress on the work of the milk stations, on the increase in their number and on the entire work of the Department of Child Hygiene. When the fusionists came into office this division of the Health Department was receiving a budget allowance of $348,190, while it is now receiving $600,000, but the elimination of graft and waste has more than made up for the increased appropriation to this work. The argument closes with an appeal to voters to continue the anti-Tammany control of the board of estimate and apportionment in behalf of the public health.

Little Italy Fighting Flies.—Under the newly organized Bureau of Public Health and Hygiene of the Association for Improving the Condition of the Poor an interesting experiment is being conducted in the heart of the Italian population of the upper East Side. Through the generosity of Mrs. A. A. Anderson, $2,000 has been put at the disposal of the association in order to eliminate as far as possible all flies from one block. Screens are furnished for all windows in the block and a special inspector from the Department of Health keeps unusually careful watch over the sanitary conditions of that block and the neighboring ones. It is hoped that a comparison of the infant mortality of this block with those in which no such careful elimination of the fly is striven for will prove the part that this pest plays in the high death rate of babies. Fly traps, fly papers and fly swatters are also furnished to the dwellers in this neighborhood and disinfectants to the owners of stables. Accurate statistics are being kept for the block and the results of the experiment will be announced at the end of ten weeks from the initiation of measures against the fly.

OHIO

Salvation Army Opens Dispensary.—A free surgical dispensary has been opened by the Salvation Army in Columbus. Among the members of the staff are Drs. D. G. Sanor, A. C. Miller, Robert Leach and Caspar H. Benson.

Tuberculosis Farm Sold.—The tuberculosis farm purchased by Miami and Darke counties two years ago, for $15,000, on which it has been intended to erect a bi-county tuberculosis hospital (but this was prevented by legal action), was sold recently for $7,300.

PENNSYLVANIA

Automobile Ambulance for Chester Hospital.—The Chester Hospital has received its automobile ambulance, purchased through public subscriptions at a cost of $4,000.

Lectures on Health.—Dr. A. Barr Snively, Waynesboro, chairman of the Franklin County Medical Society committee on health and public instruction, reports that nearly all the schools of the county have been visited by the physicians assigned by the committee. The talks on health have been well received. The talks were on (1) necessity of fresh air; (2) need of cleanliness in person and surroundings; (3) risk of personal contact with the ill, or unhealthy conditions, disease germs, infection, etc.; (4) avoidance of needless exchange of or mutual use of eating utensils, articles of toilet, etc.; (5) danger of infection from flies; (6) pollutions of drinking water and milk supplies.

Philadelphia

Personal.—Dr. Milton B. Hartzell, professor of dermatology at the University of Pennsylvania, was appointed assistant diagnostician and consultant in the Bureau of Health, August 14, to succeed Dr. Jay F. Schamberg, resigned.——Dr. J. William White sailed for Europe, August 16. He expects to be gone eight months, making a tour of the world and returning by the Panama Canal.——Dr. Charles B. Penrose sailed for Europe, August 14.

Spread of Typhoid Fever.—There were seventy-nine cases of typhoid fever reported to the Bureau of Health during the week ending August 16, an increase of fourteen over the previous week. The first week of August, thirty cases were recorded and there has been a steady increase. Nearly all the cases are in the territory subject to intermittent contamination of the water supply, where corporations and manufacturer have made connections as fire safeguards. The administration is doing everything possible to compel discontinuance of such a dual piping system. The Department of Health has issued a warning to householders, supplied by the Torresdale filter plant to boil all water used for drinking.

City Dentists Work for School Children.—The work of the city dentists at the City Hall Dispensary and at the branch in the Southwark School at Ninth and Mifflin Streets, has been of such high quality and of such volume that more branches are planned. Dr. Percy B. McCullough, chief of the dental division of child hygiene, with eight assistants, during the five months from January to the last of May of the present year, at the two dispensaries performed a total of 15,323 operations. School children are sent to the dispensary by the school medical inspectors, and these mean 90 per cent. of the whole 175,000 school children in the city. Each child receives a card on which is written the day and hours each is required to report and this is shown to the teacher, and visits to the dispensaries are attested by the dentist.

GENERAL

Bequests and Donations.—The following bequests and donations have recently been announced:

New York Orthopedic Hospital, $6,748, by the will of O. E. Schmidt.

St. John's Guild, New York City, $2,500, the Home of St. Gile the Cripple, Bronx Children's Aid Society and Society for the Prevention of Cruelty to Children, each $2,000, Brooklyn Hospital, Brooklyn Home for Consumptives and Brooklyn Nursery and Children's Hospital, each $1,000 by the will of Evelyn S. Ridgeway.

Philadelphia Home fo [illegible] $5,000 for the endowment of a free bed by the will [illegible] ey.

Four Albany (N. Y.) [illegible] by the will of Anthony N. Brady, New York City.

Presbyterian Hospital, [illegible] $100,000, one-half to be expended in building and [illegible] ntenance, $5,000 to endow a bed, in memory of [illegible]

Society [illegible] ren, $5,000 by the will of M [illegible]

Mercy [illegible] will of Mrs. Nettie Bernard, Henderson.

Rhode Island Hospital, Providence, $200,000 for the erection of the Jane [illegible] g for private patients, St. Joseph's Hospital, [illegible] the will of Jane Frances Brown.

The Ma [illegible] Hospital, Logansport, $100,000 by the will [illegible] Dykeman.

Department of Agriculture Advises that Milk be Pasteurized at Low Temperature.—In order to determine the best way of pasteurizing milk so as to kill the disease germs and yet not give the milk a cooked flavor or lessen its nutritive value, the Department of Agriculture, through its Dairy Division, has been conducting a series of experiments, treating milk at different temperatures and for different lengths of time. According to the report on these experiments in Bulletin 166 of the Bureau of Animal Industry, when milk is pasteurized at 145 F. for thirty minutes the chemical changes are so slight that it is unlikely that the protein (muscle building element) or the phosphates of lime and magnesia are rendered less digestible than they are in raw milk. Moreover, from a bacteriologic standpoint, pasteurizing at low temperatures is found to be more satisfactory than pasteurizing at high temperatures. According to Bulletins 126 and 161, where low temperatures are used the majority of bacteria that survive are lactic acid organisms which play an important part in the normal souring of milk. When milk is efficiently pasteurized at high temperatures, the bacteria which survive are largely of the putrefactive kinds, and milk so treated if kept for any length of time has a tendency to rot instead of sour. From the standpoint of economy, the technologist of the Dairy Division finds that pasteurizing at low temperatures calls for less heat. It is found that it takes about 23.5 per cent. less heat to raise milk to the temperature of 145 F. than to a temperature of 165 F. A similar gain is a saving of the ice needed, because it will require 23.5 per cent. more refrigeration to cool milk to the shipping point when it is pasteurized at the higher temperature. The department, therefore, recommends that "when market milk is pasteurized it should be heated to about 145 F. and held at that temperature for thirty minutes."

CANADA

New Officers.—Dr. Herbert J. Hamilton has been elected president of the Toronto Academy of Medicine; Dr. Harry B. Anderson, vice-president; Dr. Harry J. Smith, secretary; Dr. Wm. A. Young, treasurer.

Cigarette Smoking Increasing in Canada.—Two hundred million more cigarettes were smoked by Canadians in 1912 than in 1911, the total numbered consumed, according to a report of the Inland Revenue Department, being 975,325,501. Indeed, the consumption of tobacco and alcoholic liquors increased all around. The per capita averages are: Spirits, 1.112 gallons, compared with 1,030 in 1911; beer, 7,005 against 6.598; wine, 131 against 114; tobacco, 3.818 pounds, against 3.679 in 1911, which includes the figures for cigarettes.

New Hospital for the Insane in Ontario.—Twenty miles east of Toronto, near the town of Whitby, facing on Lake Ontario, the Ontario government is establishing a new hospital for the insane, to take the place of the institution now located in Toronto. On a site of 640 acres one of the finest institutions of this character in America is to be established. It is to have accommodation for 1,500 patients, and is so constructed that additional units for the accommodation of five hundred may be added at any time. There are to be a hospital farm, recreation grounds, amusement hall and a church. As far as possible prison labor is being used in every department of construction.

Tuberculosis Prevention in Winnipeg.—Winnipeg took up the fight against tuberculosis in 1908. Since that time proper statistics regarding the disease have been kept, notification was inaugurated, an anti-tuberculosis society established, a dispensary, hospital for advanced cases, an anti-spitting bylaw, day and night camp, open-air schools, much educational work. The provincial government now maintains a sanatorium with accommodation for about sixty patients. By a special grant from the city the General Hospital maintains a dispensary. There are city nurses who follow up cases. The Anti-Tuberculosis Society distributes much literature and has lectures delivered to the public. For advanced cases the city has a hospital of fifty beds. At least seventy-five per cent. of all the cases are now being notified. The death rate from tuberculosis has decreased in the five years from 123.4 per 100,000 of the population to 94.4.

Ontario Medical Commission.—While the citizens and medical profession of Toronto were participating in the opening of the new Toronto General Hospital, they heard of something even as much if not more interesting to the province at large. In receiving the buildings on behalf of the people of the province of Ontario, the Prime Minister, Sir James Whitney, took occasion to announce a most important departure on behalf of his government, to the effect that the government had decided to appoint a royal commission on the whole subject of medical education and the practice of medicine in the province. The object of this commission, Sir James stated, would be to acquire information whereon to base legislation for every imaginable application, so that all could be regulated and controlled in the interests of the people. The Prime Minister said that it was intended that medicine would include all plans or means of alleviating or curing human defects, disorders, diseases or wounds; and to this end an investigation will be made of the College of Physicians and Surgeons and its governing body, the Ontario Medical Council, the medical faculties of all universities, osteopathy, Christian science, dental schools, nurses' training schools, opticians and their training. When this commission is appointed and their report made, legislation will be provided of lasting benefit to the province.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Aug. 2, 1913.

British Pharmaceutical Conference: Pharmacists Demand Recognition

The fiftieth annual meeting of the British Pharmaceutical Conference has been held in London. It was attended by pharmacists from all parts of the country as well as from Australia and the Continent. The president, Mr. J. C. Umney, who is a member of the committee of reference in pharmacy which assists the pharmacopeia of the general medical council (consisting entirely of physicians), said that the British Pharmacopeia for 1914 was almost ready. The committee of reference had done its best in all loyalty to the general medical council, but he was confident that it was the last occasion on which pharmacists would aid in the revision of the British Pharmacopeia on the conditions which now obtain. Contrasting this country with various foreign countries he emphasized the fact that in the latter medicine and pharmacy were almost equally represented officially on the revision of the pharmacopeia. He suggested that the Pharmaceutical Society should consider a bill laying down the conditions under which future pharmacopeias should be revised. Among the most important papers read were those on the "Possible Iodin Standardization of Thyroids for Pharmaceutical Purposes," on the "Standardization of Opium," and "The Myrrh of Commerce."

The Government Inquiry into Nostrums

In previous letters to THE JOURNAL the evidence given at this inquiry has been published. The report is now under consideration. It is thought that one of the chief recommendations will be that the administration of the regulations affecting the sale and advertisement of proprietary articles should be carried out by one body under one department of the state, instead of under several, as at present. It will probably be agreed also to recommend that quack advertisements professing to cure some of the deadliest diseases, such as cancer and consumption, shall be prohibited and that there shall be a more rigorous censorship of the advertisements of patent medicines professing to cure peculiarly feminine complaints. Another subject with which the report may be expected to deal is whether the venders of patent medicines shall be required to accompany each article with a statement of the ingredients. It is thought unlikely that this recommendation will be made. The view which will probably be taken is that to give a statement of the formula to the state authority would meet the case.

Alarming Increase of the Non-Vaccinated

The last vaccination law (of 1907) was a great concession to antivaccinationist sentiment and exempts from penalty parents who make a declaration within four months of the birth of a child that they believe that vaccination would be prejudicial to its health. The results are shown by the following figures: In 1907 the percentage of exemptions (then obtained by an inconvenient and difficult legal process) was 6.3. In 1908 this percentage had risen to 17.3, and in 1912 to 31.6. It is true that an outbreak of small-pox has not occurred for some years, but sporadic cases are always occurring on ships which arrive in this country from all parts of the world. In this way epidemics have been generated in the past, notably a large one in Glasgow. Health officers are now much concerned at the greater prospects of the spread of the disease. All we can trust to is prompt isolation, for antivaccinationist sentiment is too strong to allow more stringent laws as to vaccination. A small-pox epidemic on a scale unknown to this generation might prove efficacious.

SEVENTEENTH INTERNATIONAL MEDICAL CONGRESS

August 6-12, 1913

(From Our London Correspondents)

The Seventeenth International Medical Congress was formally opened at the Albert Hall, August 6, by Prince Arthur of Connaught, who welcomed the delegates and members in the name of the king. The number of members attending was large, nearly 8,000. The scene was a brilliant one, enlivened by the academical costumes and military and naval uniforms of every civilized country. The presidents of the College of Physicians and the College of Surgeons and the Society of Apothecaries were attended by their mace bearers. Sir Edward Grey, Minister for Foreign Affairs, welcomed the foreign delegates on behalf of the government. He referred to the increased interest of the public in science. The risk of lay ignorance was no longer so intractable as in former generations; the opposition to scientific discoveries had given way to expectation. The public was now teachable. He would not say that with regard to all sciences. If, for instance, politics was to be called a science he would speak with considerable hesitation; not every one was teachable in a subject in which every one thought he understood.

Sir Thomas Barlow, the president of the Congress, then delivered his address. He referred to the previous congress of 1881 in London and to the great men then present who have all passed away. The president was Sir James Paget, the great clinical pathologist, and Jenner, Gull, Wilks, Gairdner, the great teachers of clinical medicine, were there. We shall not see their like again, for their careers began before the days of specialization. Hughlings Jackson, the philosophical exponent of the new neurology, was present. Hutchinson, the patient, accurate recorder of disease in many departments, characteristically was the organizer of the clinical and pathologic museum. The pioneers of abdominal surgery, Wells, Keith and Tate, were there. Huxley, the most brilliant expositor of natural science, discoursed on the relations of medicine and biology. Bowman, the founder of modern English ophthalmology, was present, and Lister, then in the zenith of his great career. Among the foreigners were von Langenbeck, Esmarch, Donders, Snellen, Baccelli, Bigelow, Austin Flint, Billings, Brown-Séquard, Charcot, Lancereaux and others. He reviewed the address of Pasteur, "who towered aloft among his contemporaries," and linked it up with the present studies of Flexner. In his reference to our progress in tropical medicine he said: "Here it is fitting that we should offer our homage to our American brethren for their splendid hygiene work in Cuba, in Panama, in the Philippines, and in Porto Rico, and for the efforts which they are organizing for a world-wide crusade against ankylostomiasis. He referred to our increasing knowledge of the protozoal diseases, to the advances in chemical pathology, and to the gradual evolution of the doctrine of thyroid insufficiency and of its therapeutics, a gradual evolution from Ord's definition of myxedema, a model of deduction, and the consequent study of the internal secretions and the therapeutic employment of organic extracts. The dietetic problems next came under review, particularly the milk problem, and diseases such as beriberi and scurvy, which are associated with a dietetic factor. The study of chronic alcoholism, of oral sepsis, and of intestinal stasis, the discovery and application of the Roentgen rays and radium, the rewriting of physiology in the light of medical knowledge were referred to. The triumphs of surgery were enumerated and the varied ways in which medicine now cooperated with economics, social legislation and philanthropy, which we sum up briefly as public health. Sir Thomas Barlow concluded by welcoming the members in the name, not only of the medical men of the British Isles, but of our brethren of the oversea dominions of the empire.

The Address in Medicine

The address in medicine was delivered by Professor Chauffard of Paris to a large and interested audience in that clear and forceful style which distinguishes the French scientist. He took for his subject "Medical Prognosis: Its Methods, Its Evolution, Its Limitations." Commencing with Hippocrates, he praised the penetrating vision of the Father of Medicine in grasping, coordinating, and interpreting the most minute details without any technical means of investigation. The modern era began with Auenbrugger and Corvisart who introduced percussion, and Laennec, the inventor of auscultation. The latter endeavored, in his own words, "to place in regard to diagnosis internal organic lesions on the same line with surgical diseases." The detection of morbid changes in the living subject gave prognosis a more certain basis. To detect the lesion in the living subject, to identify it in the cadaver and to reduce therefrom diagnosis and prognosis became the system of "organicist medicine" which lasted for more than half a century. This noble system contained much truth, but was a narrow doctrine which tended to confuse the lesion with the disease which caused it. Anatomic prognosis soon found its limitations. The succeeding stage was marked by the influence of Claude Bernard's work. With him pathology became deviated physiology, and disease became a disturbance of normal functions. Coming to the present day, what were the limitations of medical prognosis? An essential distinction must here be made between theoretical and clinical prognosis. Theoretically almost everything is known to us. In a given disease we can enumerate most of the complications or contingencies that may modify its course, but all that is book prognosis, far removed — unfortunately — from the living and individual prognosis, applied not to a disease but to a patient. How many unknown quantities are there in medical practice, and how many surprises! How little does it avail to know all the possible complications of typhoid fever if at a patient's bedside we cannot foresee the intestinal hemorrhage or the perforation which perhaps in a few hours may endanger life. Again, for the newly infected syphilitic, for the gouty subject, for the epileptic at his first attack, for countless other sick patients of all kinds, how many uncertainties for the future! When a morbid condition begins we know theoretically the various paths it may follow; but which one will it follow? That is the real prognostic problem, the solution of which too often eludes our grasp. Finally, and dominating the whole question of prognosis, there remains for us to gage the possibilities of the organism that has fallen a prey to sickness. Shall we find in it the resources necessary for overpowering disease? How much can it stand and how much can we expect of it? That is the great problem which commands and includes all the others. Are we always able to solve it? Professor Chauffard fears not.

The Address in Surgery

The address in surgery by Dr. Harvey Cushing was listened to with great attention by a large audience. It was terse and trenchant and the telling points were frequently applauded. Contrary to expectation, he did not expound some of his original work on brain surgery but took a very general subject, "Realignments in Greater Medicine: Their Effect on Surgery and the Influence of Surgery on Them." He made a strong protest against the antivivisectionist agitation which interferes with the beneficent progress of science that has done so much for humanity. Disorders which gave bread and butter to our predecessors were disappearing as small-pox disappeared after Jenner. One injection robbed diphtheria of its terrors and another meningitis. Typhoid fever was now looked on as a civic disgrace. Tuberculosis was everywhere coming under state care. Governments passed insurance acts which made public officials of the profession at one sweep. Dr. Pound of Cure-Lane was being superseded by his young disciple, Dr. Ounce of Prevention-Street. Surgery had been one of the great factors in the present realignments of medicine, for from Lister and Pasteur the great streams of progress had flowed — in the case of the individual into the art of surgery and in the case of the community into prophylactic medicine. Even the physician who for so long held himself aloof from anything savoring of handicraft returned to it with that useful instrument, the hollow needle. Paracentesis, lumbar puncture and the extraction of blood for diagnostic, or the administration of drugs and serums for therapeutic purposes by a minor surgical act are an acknowledged part of his therapeutic resources. By a strange transformation, too, he became the phlebotomist, and the venesections and cuppings, formerly the overworked province of the barber surgeon, were largely practiced by him. Billroth said about thirty years ago, "Die innere Medicin müsse mehr chirurgisch werden," and this seemed to be what was taking place.

Professor Ehrlich's Address in Pathology

At the general session in Albert Hall Friday, August 8, Professor Ehrlich of Frankfort delivered in German the Address in Pathology taking for his theme chemotherapy. After referring to the work of Jenner, Lister, Sir Patrick Manson, Ross, Castellani, Bruce, Leishman and others in the protozoal diseases, he entered into a technical explanation of the principle of chemotherapy, especially with reference to the work done in elaborating salvarsan. He explained that salvarsan had not only a direct parasiticidal action, but that immunity of parasites to such action could be accounted for only by a purely chemical diminution of their affinity, and a complete exhaustive knowledge of the various chemical peculiarities of a parasite, which he called the "therapeutic physiology of the parasitic cell," was essential for its successful chemotherapeutic treatment. Certain chemical peculiarities are found in many different kinds of parasites. In proportion as more of these chemical affinities were discovered, the greater was the possibility of successful chemotherapy. He still kept in view the idea of freeing the body of microorganisms by one or at most two injections of the proposed remedy, and in his animal experiments this principle is still being pursued. He looked forward to the extension of the principle of chemotherapy as a means of bridging the gaps which still exist in our knowledge of the treatment of some diseases. In the diseases involving protozoa and spirilla good results have already been gained. In a series of other diseases, such as small-pox, scarlatina, typhus, and perhaps also yellow fever, but above all, the infectious diseases caused by invisible germs, there is a bright prospect of success. In the common bacterial diseases due to streptococcus, staphylococcus, and the micro-organisms of typhoid, dysentery and tuberculosis he feels that the struggle is a hard one, but that success in these diseases will also be attained on the principle of chemotherapy.

Dinner by the Government to the Congress

Nothing could have been more appropriate than the welcome given to the Congress, when Lord Morley, representing the British government, entertained at dinner on Tuesday night, August 5, at the Hotel Cecil, upward of five hundred of the more eminent members of the Congress, including most, if not all, the official representatives. Lord Morley referred to the generation that had passed since the Congress last met in London (in 1881), and to the marvels in mechanics, engineering, electricity and applied chemistry that had been witnessed in the interval, but added that the new truths and new expedients in medicine and the advance in pathology and surgical practice might be counted the most striking marvel of them all. Referring to specialism, he said it was of two kinds, the narrow and the broad, and he hoped that in medicine it would ever be of the latter kind, in which priceless and indispensable work was done in regard to particular organs, parts, and regions, maladies and lesions, so that touch was not lost with organization and function as a whole. As to the relations between politics and medicine, he said that the relations of the government with the medical profession were for the moment not altogether of the easiest, but he assured his hearers that the difficulties were ephemeral and would be surmounted by and by. (This was in reference to the National Insurance Act.) He referred to the great extension of medical influence in the political and social field and in the family and administration of laws, and pointed to "a whole code of housing acts, shops acts, and health acts, including the pending Mental Deficiency Bill, and to the medical protest against the speeding up of education." He touched on the vivisection question, saying that there was a great volume of energetic opinion against unrestricted experiments on living animals, and on the venereal diseases question, saying it would be sheer moral cowardice to shrink from a large and serious inquiry into the extent, causes, and palliatives of this hideous scqurge, just as we investigate tubercle or cancer.

Sir Thomas Barlow, President of the Congress, in replying commended the selection of Lord Morley as the government spokesman, for to him we were indebted for instruction in the aims, the partial successes, and the failures of many of the leaders of liberal thought before and at the time of the French Revolution, as well as for the lessons in political philosophy drawn by him from the lives of our eminent statesmen. M. Landouzy, replying for the French-speaking members, drew a parallel between the great geniuses of England and France who had contributed to the march toward progress through the ages, and referred to depth as the distinguishing characteristic of the British temperament. Professor von Schjerning replied for Germany, and proposed the toast of the British Government.

Other Entertainments

The entertainments and excursions afforded were so numerous and lavish that it would be out of the question to attempt to describe them all. In the evening of August 6 the president of the Congress, Sir Thomas Barlow, with the officers, entertained the members of the Congress with their wives and daughters at a conversazione at the Natural History Museum, South Kensington. The museum was thrown open for inspection.

An interesting exhibit was that of Mr. J. Hartley Durrant and Lieut.-Col. W. O. Beveridge, which illustrated the investigation made under the joint auspices of the war office and the British Museum into the nature and origin of the damage occasioned by insect pests in the army biscuits.

On Thursday the Continental Anglo-American Medical Society held its annual luncheon at the Café Royal, and an invitation luncheon took place at the Royal School of Medicine for Women. St. George's and the Middlesex Hospitals were thrown open to parties of visitors, afternoon tea being provided. From 3:30 to 6 Sir Alfred Pearce Gould (the dean) and the Faculty of Medicine of the University of London gave a garden party at Regent's Park College, while the president, treasurers and governors of the Royal hospitals of Bridewell and Bethlehem held a reception in the grounds of Bethlem Hospital. In the evening a dinner was given by the Society of Apothecaries to a limited number of guests in their quaint old hall in Drury Lane. The society has a most interesting history. It was to its efforts that the first medical act, in 1815, which made the possession of a medical qualification an essential for the lawful practice of medicine, is due. The society worthily maintains the traditions and repute of the city companies as lavish yet perfect hosts, and no medical dinners are more widely renowned than those given on occasion by it. The master and wardens received the guests, which included such eminent names as those of Sir Thomas Barlow, Sir Alfred Pearce Gould, Dr. Josué, Professor Janet, Dr. Lovett, Sir Lauder Brunton, Sir Watson Cheyne, Professor Biedl, Sir Malcolm Morris, Sir David Ferrier, Sir Clifford Allbutt, Prof. Sims Woodhead, Professor Abderhalden, Professor Wenkebach, Professor Bateson, Prof. A. R. Cushny, Prof. W. Straub, Sir Arbuthnot Lane, Dr. W. J. Mayo, Professor Ehrlich, Professor Burkhardt and many others. The toast of "Our Foreign Guests" was responded to by Dr. Josué, Prof. Dr. Burckhardt and Dr. Lovett. The quaint old ceremony of drinking from the loving cup was duly performed with its historic ritual. The dinner broke up early, to allow many of the guests to attend one or other of the soirees at the Royal College of Surgeons, at which some 2,000 were present; the Royal Society of Medicine, which entertained another 1,000; the Royal Army Medical College, Milbank, where some 800 were present, and the Grocers' Company, which entertained 500 more. Besides the foregoing, which were general entertainments, there was a reception by the Medical Director General of the Royal Navy at Greenwich to the members of Naval and Military Medicine and of Tropical Medicine and Hygiene at Greenwich in the afternoon, and in the evening a soiree given by Mr. Arthur Cheattle, president of the Otological Section, receptions by the Laryngological and the Anatomical Sections, and the dinner of the Ophthalmological Section.

Friday the 8th was no less full of entertainment than the preceding day, consisting of luncheons, hospital visits and visits to many points of interest.

Sir Thomas Barlow presided at a breakfast given by the National Temperance League, and was supported by Sir Alfred Pearce Gould and Sir Victor Horsley. He referred to the change that had come over the profession in regard to the indiscriminate prescribing of alcohol, and he uttered a special warning to the profession against a "most mischievous thing" in the prevalence of medicated wines. Alcohol ordered therapeutically at all should be given by itself under the strictest conditions as to time of administration, dosage and the continuance of its use. If they believed men were better without alcohol in any form he urged them to use their influence against it.

The Archbishop of Canterbury and Mrs. Randall Davidson entertained some 350 to tea at Lambeth Palace. In the evening at 8 o'clock the Lord Mayor and corporation of the City of London gave a conversazione at the historic Guild Hall. The assembly was of extraordinary brilliancy, court dress, military and naval uniforms and academic gowns and hoods producing a truly kaleidoscopic picture.

The section entertainments were equally numerous.

Of these dinners special note should be taken of that given by the Tropical Medicine Section and the Society of Tropical Medicine and Hygiene under the presidency of Sir David Bruce. Sir David, in toasting the "Progress of Tropical Medicine" reviewed its history from the discovery in 1879 by Sir Patrick Manson of the rôle played by mosquitoes in filarial disease. He referred to Laveran's discovery of the malarial parasite between 1878 and 1880, and quoted a remark of King George that when he was a young lieutenant in the navy no sailor could go into the hospital at Malta without being struck down with Malta fever, and now, the King added, "thanks to the doctors, Malta fever is extinct." The work of Smith and Kilbourne on Texas fever in 1889, Sir Ronald Ross' work on malaria in 1898, and "the wonderful work of Reed, Carroll, Lazear and Agramonte on yellow fever" in 1900 were extolled. Finally in 1903 Colonel Sir William Leishman had uncovered the nature of the mysterious disease, kala azar.

The toast was responded to by Dr. A. Laveran, Dr. B. Hecht and Sir Patrick Manson. Sir Ronald Ross gave the toast of the visitors and guests, which was acknowledged by Professor Agramonte, Professor Blanchard, Professor Eijkman, Professor Fullerton and Dr. Wu of International Plague Commission fame.

International Medical Press Association

The International Association of the Medical Press held its first meeting in Jehangir Hall, University of London, August 5, Dr. Lucas Championnière presiding. An interesting paper was read by M. Blondel of Paris, Secretary of the Association, in which he urged a unification of medical nomenclature by an international commission, the use in all medical journals of the official terms thus to be codified, or of domestic derivatives therefrom, so that the necessary vocabulary for foreign readers of any journal might be reduced to the more common verbs, prepositions and adverbs of the language, the technical terms being practically international. He further suggested that where writers failed to observe this plan, the international terms should be inserted in parentheses after the national term used by the writer, at any rate in the title and the conclusions. Such a course, if adopted, would undoubtedly facilitate the reading of articles in foreign medical literature by those possessing even the most rudimentary knowledge of the language of publication.

Professor Posner of Berlin presented a report, which was subsequently accepted, in which he urged the formation of technical committees to supervise advertisements in the medical press, with a view to excluding such as contained false claims, and generally purifying and elevating the standard of the advertising columns.

Dr. Dejace (Belgium) was elected President on the retirement of Dr. Lucas Championnière, and Dr. Raoul Blondel (Paris) and Dr. Dawson Williams (London) were reelected respectively general secretary and treasurer. The next meeting will take place at the time and place of the next International Medical Congress.

International Association of Medical Museums

At the Royal College of Surgeons Museum, Lincoln's Inn Fields, Professor A. S. Warthin, of the University of Michigan, presided over a conference of the International Association of Medical Museums on Tuesday, June 5. Professor Warthin said there were now nearly two hundred members, by far the larger number being in America, but the foreign membership was constantly growing. The line of development had broadened. It was no longer a purely pathological museum that was contemplated, but one extending much further into all fields of medicine, particularly preventive medicine. He strongly urged the development of state or municipal traveling museums of preventive medicine and hygiene on a popular basis, such as the traveling tuberculosis museums which had given such excellent results in the United States. The success attained in the United States of America had led to the development of the traveling museums so as to include besides tuberculosis the prevention of typhoid and other transmissible diseases. Sir William Osler pointed out the geographical difficulty in the international development of the association and suggested the formation of a central bureau to control the different branches in various countries, but each country must have autonomy in managing its own museums. He recommended triennial meetings to be held wherever the International Medical Congress meets.

Women and the Congress

No public function of note would be complete in these days without the hallowing presence of the "suffragette," so it is comforting to note that suffragette sandwich-women paraded around the Albert Hall with placards asking "What do doctors think of woman torture? The government is murdering women." Some of them even buttonholed the doctors and essayed to lay their grievances before them, but apparently they tackled foreigners for the most part, who obviously failed to comprehend what they said. Later the following inscription was chalked on the sidewalk in front of the principal entrances to the various halls: "MM. les Médecins, que pensez-vous de la torture imposée sur les femmes par le gouvernement anglais?" and a similar question in German.

The progress of woman's emancipation was, however, marked in a practical fashion in the present congress. In 1881 the *Lancet* reminded the forty-three duly qualified medical women who protested against the exclusion of medical women from membership, that "the Congress is a voluntary assemblage of medical men for a certain purpose, and those who are not asked to join suffer no infringement of their rights." But women doctors abounded at the present congress, and several of them took a distinguished part in the proceedings.

Degrees for American Surgeons

An event of special interest to American medicine took place on the opening day when the Royal College of Surgeons conferred the honorary fellowship of the college on fifteen eminent foreigners, among them Dr. G. W. Crile, Dr. Harvey Cushing, Dr. W. J. Mayo and Dr. J. B. Murphy. The newly elected fellows were entertained at dinner in the college.

The Section Proceedings

A comparison of this congress with the previous London Congress of 1881 shows great differences. In the latter there were only a little over 3,000 members — less than half of the number present on the opening day and the work was divided into fifteen sections. In this congress there were twenty-three sections. While many of the famous medical men of the world were present, it cannot be said that the congress revealed any important discovery, its work consisted largely of stock taking of recent medical progress, showing what new views were becoming accepted. Many of the papers were of great interest and importance, but there were also many which were not and were but a repetition of what was well known, or were crude and unconvincing. The program was generally overcrowded and speakers often raced the clock to get in what they wanted to say in the allotted time, and were brought to a premature end by the chairman's bell. As in all medical [illegible] capacity of even those who were eminent and [illegible] say, to say it properly and concisely, was [illegible] The fifteen minutes allotted to a speaker if properly used was in most cases amply sufficient to present his conclusions and his reasons for them, but want of conciseness of expression as well as want of judgment in suppressing unnecessary details prevented this. Instead of brief but sufficient general description worse than useless details which only wearied the audience were presented. It is curious that no one seems to trouble about the reform of this universal evil. The man who could compel the education of medical authors in the art of conciseness, before they be permitted to speak or write, would deserve a place in history among the benefactors of humanity.

Section on Medicine

The proceeds of the section on medicine were opened Thursday, August 7, by the president, Prof. Sir William Osler, Bart., with a few introductory observations. Over two hundred members of the section were present, and the first paper heard was Professor Banti's (Florence) exhaustive account of the clinical aspects of hemolysis, more particularly as they affected the spleen. In many patients with splenomegaly, as he pointed out recent work tends to prove that the anemia in such patients is due to excessive hemolysis in the pathologically enlarged spleen. He referred to the association of splenomegaly with cirrhosis, a combination that is familiar, by name if not *de visu*, to most medical men as Banti's disease. He summarized the work that has been done so extensively on the continent of Europe with hemolytic serums, and noted that the spleens of animals treated with such serums showed changes very similar to those met with in the splenomegaly with anemia of human beings.

Professor Chauffard of Paris ascribed an important rôle to the spleen in all the human diseases that were characterized by the occurrence of hemolysis. He did good service by bringing out the fact that the enlargement of the spleen habitual in these cases might be either the cause of the hemolysis, or its effect. If it was the cause of the hemolysis, clearly the condition would be improved and the anemia cured by the operation of removing the spleen. If, on the other hand, it were an effect of the hemolysis, splenectomy would only accelerate the patient's passage to the grave. How can one distinguish between the two cases, he asked, and how can one know when splenectomy is advisable? These questions he could not answer with any confidence himself, and he called for further investigation and information on the results of removal of the spleen: animal experiments had given contradictory results in the hands of different observers.

An interesting paper on "Duodenal and Pyloric Ulcers" was read by Prof. C. A. Ewald of Berlin. Professor Ewald pronounced himself horrified by the statistics of British and American surgeons, who claim to have proved that duodenal ulcer is a commoner, perhaps a far commoner, complaint than ulcer of the stomach. How could such statements be justified? he asked. Reference to the post-mortem room statistics afforded no support to such surgical statements; in his own clinic he had treated 532 cases of gastric ulcer and eighty-two of duodenal ulcer during the three years, 1910, 1911, 1912, and he quoted continental (European) statistics to prove that as a matter of fact gastric ulcer is quite six times as common as ulcer of the duodenum. Yet he was at pains to acquit the surgeons of intentional error in their statistics, and explained that their mistake arose from the fact that they only meet with the severe and the chronic cases of such ulceration, on the one hand, and on the other from their habit of including among duodenal ulcers those ulcers that extend from the pylorus. Professor Ewald doubted whether regional or occupational factors could afford an explanation of the surgical statistics and the inferences surgeons drew from them. He further felt himself bound to dissent very strongly from the dictum of Sir Berkeley Moynihan, who said that a careful history sufficed to make the diagnosis of duodenal ulcer, and that it was not necessary to examine the patient before coming to a positive conclusion. Professor Ewald pointed out how patients with cholecystitis, appendicitis, tabes with gastric crises, or even severe neurasthenia, might find themselves exposed to operations for the cure of non-existent duodenal ulcers, should such diagnostic criteria as Moynihan's be accepted as adequate. He himself laid stress on three or four points in particular, in the diagnosis of duodenal ulcer: (1) The long duration of the case, and the recurrence of pain two or more hours after food had been taken; (2) the pressure of blood, manifest or occult, in the stools; repeated examinations might be called for; (3) hyperchlorhydria, which is almost constantly found, even when the stomach is free from food; (4) skiagraphic examination of the stomach after a bismuth meal; the duodenum fills up with unusual rapidity, the stomach is often not empty after six hours, the gastric peristalsis is abnormally forcible, and the stomach itself is frequently displaced downward and to the right. Dr. Max Einhorn and Prof. N. E. Brill of New York both disclaimed the surgical statistics to which Professor Ewald had taken such exception, so far as America was concerned, while Prof. R. Saundby (Birmingham), though advocating operative treatment in a large number of the cases of duodenal ulcer, expressed himself as not prepared to go as far in this direction as certain eminent British surgeons.

In the afternoon Prof. N. E. Brill of New York read an interesting paper on "An Acute Infectious Disease Similar to and Perhaps a Modified Form of Typhus Fever." He laid stress on the complete absence of contagiousness characterizing the complaint; typhus fever, on the other hand, was notoriously catching. The new complaint, again, was practically never fatal—out of some 400 cases he had collected only one had died. Typhus fever, on the other hand, was fatal to from 18 to 25 per cent. of the patients as a rule; in even the mildest of the typhus epidemics hitherto described the mortality had been as high as from 5 to 8 per cent. No general discussion of the paper took place, owing to the lateness of the hour. But the upshot of the whole matter was that Professor Brill's disease may in all probability be set down as an unusually mild and benign form of typhus fever.

(To be continued)

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Aug. 1, 1913.

Fraud in Connection with Industrial Accidents

I have spoken of the disgraceful behavior of certain "clinics" for industrial accidents, which have tried in all sorts of ways to get hold of injured working men. The Committee of the Chamber of Deputies on Insurance and Social Welfare has taken up the matter. It decided to introduce the following clause into the bill relating to occupational diseases which is now under discussion: "Any one who by threats, gifts, promises of money, rebate on medical fees or charges for druggist's supplies, made in industrial accidents to syndicates or companies or heads of business enterprises or insurance companies, or any other person, has enticed or attempted to entice the victims of industrial accidents or occupational diseases into any clinic or doctor's office or drugstore and thus has limited or attempted to limit the freedom of the workman in choosing his physician or druggist, shall be subject to a fine of from 100 to 500 francs (about $20 to $100) and to an imprisonment of three days to three months."

Nurses in Religious Orders and Hospital Services

About a year and a half ago (THE JOURNAL, Jan. 27, 1912, p. 289) I mentioned the commotion caused in the medical profession by the decision of the government requiring the substitution of lay nurses for the sisters of the Order of St. Martha in the sanatorium at Périgueux. The Union des Syndicats médicaux de France joined with the physicians of Dordogne in protesting to the government against interference with the free choice of the staff in private clinics and urged the medical representatives in parliament to present a bill on the subject. The Association générale des médecins de France also committed itself to the same point of view. In the hospitals belonging to the city and general government, moreover, there has been an increasing sentiment lately against laicization. The mayor of Marseilles recently received a delegation which presented a petition signed by more than 130,000 persons, demanding the restoration of the members of religious orders in the municipal hospitals there. A municipal councilor of Paris, M. de Puymaigre, has proposed the admission of members of religious orders to the hospitals of the city of Paris and the department of the Seine on the grounds of the difficulty of obtaining lay nurses for the slender salaries offered. Even if the lay staff is retained, the hospitals ought not to be deprived of the service of the religious orders, which is the more desirable because the sisters are content with a very modest salary. Some hospitals might be served by members of religious orders and others by lay nurses, so that the patient might have his choice of nurses. The Syndicat médical de Paris and the Syndicat des médecins de la Seine have approved the proposal. At Grenoble a petition for the restoration of the sisters, bearing 25,000 signatures, has been rejected by the board of administration of the hospitals of that city, which declares itself quite satisfied with the lay nurses, to whose good qualities the board bears testimony.

The Sale of Drugs by Midwives

A midwife at Saulnes was arrested for abortion. Her house was searched and various drugs were found in it. She was acquitted of illegal practice of pharmacy on the ground that the law permits physicians or officers of health to keep drugs in localities where there is no drugstore. Thus the court admitted that midwives were officers of health. The court of appeals at Nancy has reversed the judgment and fined the midwife $100 (500 francs) on the ground that midwives, being licensed to practice only their own specialty, are not officers of health and therefore can handle only drugs necessary for his specialty.

Death of Professor Coyne

The death of Dr. Paul Coyne, former professor in the Faculté de médecine de Bordeaux and national correspondent of the Académie de médecine, is reported.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, July 25, 1913.

Municipal Purchase of Mesothorium

On favorable reports as to the therapeutic effects of mesothorium in cancer, the communal authorities of Essen have determined to purchase 200 mg. of the preparation. Half of the necessary sum, $10,000 (40,000 marks), has been raised by private subscription and the rest has been appropriated by the communal authorities.

Colonial Prizes

The well-known wholesale merchant, Woermann of Hamburg, whose father had a great share in the founding of the first German-African colony, has offered the faculty of the Colonial Institute at Hamburg $1,500 (6,000 marks) as a prize for the best discussion of the question, "By what practical means can an increase of the birth-rate and a reduction of the infant mortality among the native colored population—the most important economic factor of the colonies—be secured?" In addition to the medical aspects of the question, the work must include consideration of the religious, ethnographic and economic relations which may influence the birth-rate and infant mortality among the natives of the colonies, and in addition must include practical suggestions for increasing the birth-rate and reducing the infant mortality among the native colored population. The investigation need not be extended to all of the protected districts. Articles which are confined to one district may be admitted for competition. The articles must be written in the German language, and reach the faculty of the Colonial Institute at Hamburg, Dec. 31, 1914, at the latest.

International Health Office in Jerusalem

An international health bureau has been founded at Jerusalem by the German Society for combating malaria in Jerusalem *(Deutsche Gesellschaft zur Bekämpfung der Malaria in Jerusalem)*, the Jewish health office (Nathan Straus foundation), and an association of Jewish physicians and sanitarians *(Gesellschaft jüdischer Aerzte und Naturwissenschaftler für sanitäre Interessen)*. Departments are provided for malaria, for hygiene, a serologic and Pasteur antirabic institute, and a bacteriologic and tuberculous department. Professor Mühlens is director of the health office.

International Conference on Tuberculosis

The International Conference on Tuberculosis will occur in Berlin, October 22-25, with Bourgeois of Paris as president. With it there will be two weeks of educational trips for information in hygiene of which one will be to Munich, Nurnberg, Heidelberg, Baden-Baden, Frankfort and Giessen, and the other to Düsseldorf, München-Gladbach, Leverkusen, Essen, Hamburg and Berlin. Those intending to be present should send announcements to the general secretary, Professor Pannwirt, 12 Schönebergerufer, Berlin.

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, Aug. 5, 1913.

Professor His Refuses to Come to Vienna

Professor His, who was asked to accept the appointment of director of the medical clinic as successor of von Noorden, has decided to decline the honor. The reasons given by him—disinclination of the family—are surely not the only ones, and there must be something else which causes so many eminent scientists—Strümpell, von Noorden, Abderhalden, His—to refuse to come here, since a call to Vienna was once regarded as the highest honor. The trend of opinion now among the faculty is that an inland man ought to be called; but since some of the most eminent candidates are Jews or come from Jewish stock the religious prejudices here will not permit their being appointed. Therefore the number of inland men fit to accept such a call is very small indeed, from racial and religious points of view.

Small-Pox Mortality in Austria Since 1886

Statistical data dealing with the mortality from small-pox are available for Austria since about 1886, when practically compulsory vaccination was introduced with the effect that within a few years the overwhelming majority of the population (about 85 per cent.) were vaccinated; and now more than 98 per cent. of the population have been vaccinated at least once during their life. The results are clearly visible in the returns of the mortality tables of the Registrar General. In the year 1886 10,163 persons died in Austria from small-pox, or 434 per million inhabitants. The average mortality from this source in the five years (1891-1895) following the first lustrum was 4,484 per year, or 180 per million, meaning a drop to less than a half of the original figures. The next five years averaged only 1,427 deaths per year, or 60 per million (one third of the figure stated for the preceding period). A still more rapid fall is noted in the next five years (1901-1905), averaging 36 deaths, or 13 per million. The figures for 1906 were 39 deaths; for 1907, 41; for 1908, 14 deaths; for 1909, 13, and for 1910, 5, averaging for these five years 22 deaths annually, or 0.8 per million of inhabitants. If we compare these figures with the data obtained for instance from Great Britain, we find the most instructive fact that there occurred three epidemics of small-pox in the United Kingdom within this period (1887-1888, 1893-1894 and 1902-1904). The last-mentioned epidemic alone claimed 4,731 victims, and the explanation is to be found in the fact that numerous persons availed themselves of the opportunity offered them by the law by declaring their "conscientious objection" against vaccination and thus being exempt from compulsion to submit to it. In Austria, on the other hand, most of the younger generation of doctors have not seen a real small-pox case except in pictures of a dermatologic atlas. Only in seaports where now and then an imported case is brought into the quarantine hospital do we occasionally receive instruction of this kind. The cases observed inland within the last few years were all traced to Turkey and Italy, whence travelers had come hither already infected.

The War and the Cholera in the Balkans

The new Balkan War has again caused an outbreak of cholera in the war district, and the wounded soldiers being sent home or into the rear hospitals have spread the disease all over the fighting countries. Especially in Servia and Bulgaria there are numerous cases, although they are officially not known. One of the most fruitful sources of infection seems to be the abundance of flies; at least all soldiers and war correspondents are convinced of it, even if the scientific proof has not yet been obtained. Myriads of flies feed on the heaps of corpses of the slain of those who have died from cholera and remained unburied for days, and they multiply and infest everything in the fearful heat raging in the Balkans just now. Reports from the new Red Cross missions always point out the calamity encountered by the multitude of flies. Stringent precautions have been taken on the Austrian frontier to guard against the entrance of cholera. The wet, cool weather prevailing in central Europe has assisted the officers of the boards of health in the endeavor to keep the disease out hitherto.

The Danger of Whooping-Cough and Other Infectious Diseases

Statistics regarding the fatal cases of whooping-cough, compared with the mortality of scarlatina, measles and diphtheria, show the startling fact that the first-named disease twenty years ago was more dangerous than even scarlet fever, and that now it still is worse than diphtheria. The following figures are taken from the official report of the Austrian Board of Health and published by Dr. Langer in the *Oesterreichische Sanitätswesen* for 1913, No. 21.

REPORTED FATAL CASES IN AUSTRIA

Year	Whooping-Cough	Scarlatina	Measles	Diphtheria
1890	27,274	12,158	15,182	28,514
1908	8,714	14,366	7,929	7,924

In these figures the numerous deaths due to complications of whooping-cough are not considered. Special attention should therefore be paid to this dangerous disease, as not so much change of air as pure air alone is necessary for the cure of the attacks.

Marriages

WARD BOLEYN MACCAFFRY, M.D., U. S. P. H. S., Fort Monroe, Va., to Miss Laura Garside Stott of Philadelphia, in New York City, July 9.

JOHN W. ELDER, M.D., Des Moines, Ia., to Miss Ethel Eleanor Chamberlin of Adel, Ia., at Des Moines, August 8.

CHARLES JOHN BOEHS, M.D., M.R.C., U. S. A., to Miss Hattie Collier of Houston, Tex., at San Francisco, July 31.

THOMAS JOHN EMBERTON HOLMES, M.D., Paterson, N. J., to Miss Martha M. La Paugh of Port Jarvis, N. Y., June 9.

HERBERT EDWIN WILKINSON, M.D., to Miss Pheby St. Thomas, both of Eagle Lake, Minn., August 4.

CLAUDE GRANVILLE CRANE, M.D., to Miss Elizabeth K. Thistle, both of Brooklyn, N. Y., August 7.

LOUIS JOHN KAUFFMANN, M.D., Millville, N. J., to Miss Maria G. Keenan of Philadelphia, August 6.

ALVAH LEWIS SAWYER, M.D., Chicago, to Miss Marion L. Messer of Beloit, Wis., June 21.

EDWARD J. DEIBERT, M.D., to Miss Flora E. Bader, both of Hillerton, Pa., August 5.

ALLAN MCNALLY, M.D., to Miss Ida L. Sanaman, both of Louisville, August 2.

Deaths

Alfred Watt, M.D. University of Toronto, Ont., 1890; superintendent of the Government Quarantine Station at William Head, B. C.; is said to have committed suicide July 27 by leaping from the third story window of a hospital in Seattle.

Ezekiel Y. Salmon, M.D. University of Nashville, Tenn., 1857; surgeon in the Confederate Service during the Civil War and later a practitioner of Nashville and Lynchburg, Tenn.; died at his home in the latter city, July 8, aged 83.

Giovanni C. D. Caruso, M.D. Royal University of Naples, 1888; a fellow of the American Medical Association; who had devoted much attention to hygiene; died at his home in Cleveland, June 27, from cerebral hemorrhage, aged 52.

John Baker Swift, M.D. Harvard Medical School, 1877; a member of the Massachusetts Medical Society; for one year port physician of Boston; gynecologist to Carney Hospital; died at his home in Boston, July 29, aged 59.

Ruth A. French, M.D. Woman's Medical College of Pennsylvania, Philadelphia, 1867; at one time professor of anatomy in her alma mater; formerly of Petaluma, Cal.; died at her home in Santiago, June 23, aged 74.

Emma E. Richards, M.D. Woman's Medical College of Pennsylvania, Philadelphia, 1886; for three years school director, of Norristown, Pa.; died in her home at Wyomissing, Pa., July 31, from neurasthenia, aged 63.

Anson Cordian Smith (license, Minn., 1887); of Cleveland and Eagle Lake, Minn.; a practitioner for more than half a century; a veteran of the Civil War; died at the home of his son in Eagle Lake, July 20, aged 79.

Robert Henry Bigger, M.D. University of Victoria College, Coburg, Ont., 1866; for twenty-seven years a practitioner of Indianapolis, and later of Carrollton and Mount Vernon, Ill.; died in Los Angeles, July 27.

David Shoemaker, M.D. Cooper Medical College, San Francisco, 1891; a member of the Medical Society of the State of California; died suddenly at his home in Auburn, Cal., July 19, from heart disease, aged 48.

J. Benjamin Jones (license, South Carolina, years of practice); a practitioner since 1879; for many years a practitioner of Laurens, S. C.; died at the home of his nephew in Greenville, S. C., July 19, aged 57.

William Edward Alumbaugh, M. D. Hahnemann Medical College of the Pacific, San Francisco, 1889; formerly of Watsonville, Cal.; died at his home in Napa, Cal., July 6, from arteriosclerosis, aged 76.

George Victor Winter, M.D. Northwestern University Medical School, Chicago, 1911; of Albany, Minn.; died in a hospital in St. Paul, July 29, a week after an operation for appendicitis, aged 33.

Harvey Allen Snyder, M.D. Cleveland Homeopathic Medical College, 1904; at one time a member of the Barberton (O.) school board; died at his home in that city, July 31, from pneumonia, aged 44.

Bernard Aloysius Duhigg, M.D. Long Island College Hospital, Brooklyn, 1894; formerly of Bath Beach, Brooklyn, N. Y.; died at the residence of his brother at St. James, L. I., July 29, aged 41.

Edward Francis Dowd, M.D. Harvard Medical School, 1898; famous while in college as a baseball pitcher; died at his home in Waltham, Mass., from pneumonia, July 26, aged 38.

David Howland Cannon, M.D. Harvard Medical School, 1873; for many years chairman of the Mattapoisett (Mass.) Board of Health; died at his home in that place, July 2, aged 69.

James J. Burch, M.D. Medical College of Georgia, Augusta, 1893; of Double Branches, Ga.; died suddenly in Elberton, Ga., July 22, from cerebral hemorrhage, aged 50.

George Porterfield Morrison, M.D. New York University, New York City, 1881; died at his home in Martinsburg, W. Va., July 24, from cerebral hemorrhage aged 59.

Walter A. Reynard, M.D. Georgetown University, Washington, D. C., 1907; died at his home in Stamford, Conn., July 30, from ptomain poisoning, aged 27.

Ira L. Jones, M.D. University of Buffalo, N. Y., 1864; one of the oldest practitioners of Oswego County, N. Y.; died at his home in Minetto, July 30, aged 81.

Henry V. Worley, M.D. Rush Medical College, 1880; an early settler of Pierce City, Mo.; died at the home of his daughter in that city, July 31, aged 62.

Hutcheson James Nash, M.D. University of Toronto, Ont., 1861; medical officer of health for Forest, Ont.; died at his home in that place, May 17, aged 67.

Samuel S. Boyer, M.D. Jefferson Medical College, 1864; a surgeon of volunteers during the Civil War; died at his home in Washington, D. C., aged 76.

Fred M. Klussman, M.D. Kentucky School of Medicine, Louisville, 1897; died in his apartment in Spokane, Wash., July 21, from heart disease, aged 38.

Neil McIntyre, M.D. University of Toronto, Ont., 1886; of Phoenix, Ariz.; died at his summer home in LaJolla, Cal., July 26, aged 71.

Eliza M. Miller, M.D. Hahnemann Medical College, Chicago, 1886; died at her home in Los Angeles, July 6, from paralysis, aged 75.

Hamilton W. Dimmitt, M.D. Medical College of Ohio, Cincinnati, 1888; died at his home in Germantown, Ky., July 17, aged 46.

Thomas Henry Stark, M.D. Trinity Medical College, Toronto, 1881; died at his home in Toronto, June 9, from angina pectoris.

Adolph Moeller, M.D. Rush Medical College, 1888; formerly of Milwaukee; died in Alhambra, Cal., July 27, aged 53.

Jerrold D. Ball, M.D. University of Toronto, Ont., 1874; died recently at his home in Toronto

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

SOME MISCELLANEOUS NOSTRUMS

Himalya; the Kola Compound

Though advertised as "Nature's Great Specific for the Cure of Asthma," the chemists of the North Dakota Agricultural Experiment Station reported "Himalya, the Kola Compound" to be "a weak hydro-alcoholic solution of potassium iodid, flavored with peppermint and licorice and colored with caramel." While the name would indicate that the active ingredient of the stuff was kola, the chemists stated that "little, if any, kola enters into the preparation." The preparation contains more than 9 per cent. alcohol, yet the exploiters recommend it to be taken with whisky! The stuff was sold for $2 a bottle; "it could be prepared," according to the North Dakota chemists, "by the average pharmacist for, say, about a dime."

Mrs. Bradley's Face Bleach

The claims made for this stuff, which emanates from Minneapolis, are that it "removes moth, tan, freckles, pimples, blackheads, prevents wrinkles, oiliness and aging of the skin." What else it does is left to the seeker after beauty to learn by experience. Its ingredients were reported by the North Dakota Government Agricultural Experiment Station to be Epsom salts (magnesium sulphate) and corrosive sublimate (mercuric chlorid). A more detailed analysis appeared in the *Druggists' Circular*, March, 1913:

Anhydrous magnesium sulphate	45.7 per cent.
Sodium chlorid (common salt)	9.7 per cent.
Mercuric chlorid (corrosive sublimate)	23.6 per cent.
Water	23 per cent.

Dr. T. Felix Gouraud's Oriental Cream or Magical Beautifier

As long ago as 1907, Dr. T. Felix Gouraud's Oriental Cream or Magical Beautifier was analyzed by the state chemists of New Hampshire, who reported that it consisted of "approximately one-half ounce of calomel suspended in a short half-pint of water." More recently—in 1912—it has been analyzed by the chemists of the Connecticut Agricultural Experiment Station, whose report is practically identical with that of the New Hampshire chemists. Some of the claims made for this simple mixture are:

> "Purifies as well as beautifies the skin. No other cosmetic will do it."
>
> "Removes tan, pimples, freckles, moth patches, rash and skin diseases and every blemish on beauty and defies detection."

An eight-ounce bottle of this preparation costs 98 cents. As the Connecticut chemists say: "The amount of calomel in a bottle of this substance can be bought at retail for about 6 cents; the remaining 92 cents is the charge for a half-*pint of water*."

Cat-Er-No "Soules"

On this article, which is said to be made by the Soule Medical Company, Minneapolis, the chemists of the North Dakota Experiment Station reported: "Sample was an aqueous solution of menthol with just enough of a vegetable drug present to give it a color. There was less than 0.1 of 1 per cent. of total solids. Sample would be of little value as a catarrh cure."

Ely's Liquid Cream Balm

This preparation, which is sold as a "remedy for catarrh, catarrhal deafness, hay fever, cold in the head," is a pinkish liquid having the odor of thymol and menthol. It was analyzed by the chemists of the Connecticut Agricultural Experiment Station, who reported that it "appears to consist essentially of liquid petrolatum with small quantities of thymol and menthol." The chemists further asserted that a bottle of

Ely's Liquid Cream Balm costing 69 cents contains about half a-cent's worth of liquid petrolatum.

Dr. Boskano's Cough and Lung Syrup

Still another "new remedy for the positive cure of consumption, coughs, colds, etc." As long ago as 1908 the Kansas State Board of Health showed this remedy to be misbranded, describing it as "a saccharin solution of expectorant drugs with tar and chloroform." In 1911 it was analyzed by the chemists of the North Dakota Agricultural Experiment Station, who reported that it "appears to be made from an inferior grade of honey, syrup of tar, chloroform, alcohol and morphin." The analyst noted that practically all the morphin was found not in the solution but in the sediment which was deposited on the sides and bottom of the bottle; yet the mixture was put up without a "shake" label! He concludes, "The dead fly found in the liquid could scarcely *merit the 'hearty approval of all physicians and medical experts'* which is claimed in the circular accompanying this remedy."

Vêritable Grains de Santê du Docteur Franck

Since the beginning of the nineteenth century, according to the descriptive leaflet, these "Grains of Health" have been preventing "typhoid congestions," and various other woes which arise from impaired intestinal functions. Their value is defined as "*stomachic and laxative, depurgative, purgative* and antiseptic." The "grains" were examined by the chemists of the Connecticut Agricultural Experiment Station, 1912, who reported that the pills appeared to be essentially aloes and cost at the rate of $33.19 a pound.

Dr. Bloomer's Catarrh Remedy

This preparation, hailing from Altoona, Ga., comes in cigarette form. Analyzed by the chemists of the North Dakota Agricultural Experiment Station it was reported to contain "*chamomile flowers* over 50 per cent., powdered cubeb, fennel seed and a few other powdered vegetable substances."

Schenck's Pulmonic Syrup

A sample of this "seventy-year-old Standard Remedy for Consumption, Coughs, Colds, Diseases of the Lungs and Respiratory Organs," was analyzed by the chemists of the Connecticut Agricultural Experiment Station, who reported: "This remarkable remedy for consumption is essentially a winter-green-flavored mixture of saccharin syrups, 96.4 per cent. of the solids consisting of sugars. It is hard to believe that the virtue of this material rests in the 2.7 per cent. of undetermined solids (possibly vinegar of squills). It is recognized that a rich and nutritious diet is essential in the treatment of consumption, and it is true that this substance, with nearly 73 per cent. of sugar, is highly nutritious, and yet one can scarcely recommend the purchase of such a preparation at the rate of $2.50 a quart, when molasses is obtainable at 50 to 60 cents a gallon."

Dr. J. H. McLean's Tar Wine Lung Balsam

"Will cure coughs, colds, bronchitis, consumption, asthma, throat and lung troubles," read the label; but, according to state chemists of North Dakota, analysis of this preparation would indicate that it "is nothing but a weak syrup of tar, containing about 15 per cent. by volume of ethyl alcohol." The examination is also reported to have shown that "the base of the preparation is not wine, as the label would lead one to believe." The report closes: "Thus the remedial agents in this preparation 'will cure consumption,' etc., are sugar and alcohol."

Dr. Gun's Pain Expeller

This product, which is said to be prepared by C. W. Beggs Manufacturing Co., Chicago, was declared misbranded by the Colorado State Board of Health in 1909. One of the reasons for this action on the part of the Colorado officials was that the stuff was labeled "free from any dangerous ingredients," when, as a matter of fact, it contained opium. The product was again examined by the chemists of the North Dakota Agricultural Experiment Station, who reported in 1911 that two bottles of the preparation, bought in different parts of the state, showed variation in the proportions of the ingredients. The product was found to contain alcohol varying in amount between 50 and 60 per cent. and to have from 1 1/5 to 1 3/4 grains of opium to the ounce, while the presence of camphor and capsicum was determined.

Correspondence

Origin of the Sign Which Stands for Recipe

To the Editor:—In view of the general interest in the question of the origin of the sign placed at the head of a prescription, I wish to put before the readers of The Journal an opinion which I have obtained from O. F. Long, professor of Latin, Northwestern University. The following correspondence will make the matter clear.

Hugh McGuigan, M.D., Chicago.

Dear Professor Long:

A prescription commences with the symbol ℞, representing the Latin word *recipe.* The origin of the ligature is a source of discussion and confusion to many. Most books on prescription-writing state that in ancient times it was the custom to preface a prescription with a pious invocation to Jupiter, or some guardian deity. The prayers finally became abbreviated until they were expressed by ♃, the astronomical sign for Jupiter. The ligature or stroke across the letter ℞, which heads the modern prescription, is said to be a relic of this heathen custom.

Is there any basis for this teaching? Some recent writers state that it is merely a sign of abbreviation used by writers of Latin manuscripts. Very few, if any, medical writers are qualified to pass an opinion on this subject; if therefore it does not involve too much time on your part, I should like to have your opinion on it.

Hugh McGuigan.

Dear Dr. McGuigan:

The abbreviations used in Latin manuscripts go back, of course, to various origins, and various methods are used. There is an ancient system of shorthand writing known as Notae *Tironianae* which is responsible for some of the kinds of abbreviations used. The particular abbreviation represented by this ligature is not uncommon for various endings, as the following words may illustrate:

Word	Abbreviation
Feria	Illorum	
Accipe	
Rerum	
Anus	
Sarisburia	

In the "Dizionario di Abbreviature latine ed italiane," by Adriano Cappelli, published at Milan, second edition, 1912, there are various abbreviations reported from Latin manuscripts that illustrate these points, and I select from *pp.* 322 and 323 the following that will be of particular interest in this connection:

Word	Abbreviation
Respondere	Reverendo Domino	
Rubrica	
Reverendi	

The exact word which we are after, "recipe," is abbreviated on p. 323 as follows, Rec, and is noted as a medical term. You will see that here the ligature is *not* used. This is precisely what we find to be the case in all of these abbreviations under the letter R, regardless of the meaning of the word. Sometimes the stroke is put across the tail of the R. and sometimes not. I do not believe that the facts afford any basis for the theory of an invocation to Jupiter.

O. F. Long.

The Cross-Roads Surgeon

To the Editor:—I have been very much interested in the discussion of the paper on "Posterior Gastrojejunostomy in Acute Perforative Ulcer of the Stomach and Duodenum," presented by Dr. John B. Deaver at the Minneapolis meeting of the American Medical Association. While I fully realize the necessity of emphasizing the responsibility assumed in attempting to operate in cases of this character, I regret the somewhat personal character of the discussion when reference was made to cross-roads surgeons. Less than a century ago the superstition was prevalent that all major operations must of necessity be performed in a hospital ward; later, that a celiotomy must of necessity go to Philadelphia; and subsequent to this, that only large cities and extraordinarily well-equipped hospitals could be used for performing these grave operations. However, modern surgery of the best and most successful type is being done by these cross-roads surgeons who are criticized in this discussion.

The statement that great operations should be performed only by those surgeons who have spent much time in fitting themselves for this work sounds very well, but where can a surgeon qualify if he does not develop the resources at hand? And what will the public do when all those now fitted to perform these operations are dead?

The gist of the discussion, with which I fully agree, is that anyone who undertakes operations of this character must be honest with himself and must have sound judgment, which he should carefully exercise in the interest of his patients. Many of the so-called cross-roads surgeons have this quality, and are honestly working in the best interest of their patients, while they are developing with the experience that comes to them. The point I would make is that not all physicians of ability live in the city, there are some at the cross-roads.

Paul Peniston, M.D., Newnan, Ga.

Need for Inexpensive Obstetric Nurses

To the Editor:—Something should be done to enable women of scanty means to receive decent care during confinement. Everything is being done in the way of intelligent care for the women who are giving birth to illegitimate children. This is as it should be, for although it is a stain on the woman's virtue, she is not so vile as the married woman who murders her offspring in her womb. The honest wife of the working man has to "grunt and sweat under her heavy load" and if she dies for want of care the blame is unjustly placed on Providence. Trained nurses cannot be obtained for the wife of the working man because the mainstay of the family cannot pay the price. There should be training schools for women who would devote their work to taking care of the working man's wife, during confinement, at a reasonable charge. The time for such study should not be longer than six months and the work taken up by widows or women over 30 years of age. Giving birth to a child is purely physiologic. In the greater number of cases a thorough knowledge of cleanliness is all that is necessary. Nowadays if the wife of the working man receives the necessary care she is saddled with a load of debt, so that her husband looks on his wife's pregnancy as a domestic calamity. In no other condition is common sense, combined with intelligent skill, so necessary. Less pawing and mauling of the woman is desirable. Meddlesome interference has laid many a woman in the cold ground. Six months' training for nurses in a lying-in hospital is sufficient for such work. The honest wife of the poor man should receive at least the same care as her erring sister.

E. T. Milligan, M.D., Detroit.

A Ratless Utopia.—A ratless country seems almost utopian, but much can be accomplished in preventing the unnecessary loss and in safeguarding the country from any possible plague invasion, by a concerted and well-sustained nation-wide crusade against the rat, similar to the "swat the fly campaign." No sporadic or individual effort will suffice.—R. H. Creel, *Pub. Health Rep.*

Medical Economics

CONTROL OF CANCER

The American Society for the Control of Cancer is a recently organized body, consisting of both laymen and physicians. Its object is the education of the public on the controllability of cancer through early diagnosis and operation. Mr. George C. Clark of New York is president. Mr. Thomas M. Debevoise, 62 Cedar Street, New York, is secretary, and Dr. Clement Cleveland of New York is chairman of the executive committee. The society has recently issued a statement to the press, setting forth its aims and plans, from which the following is abstracted:

It has long been known that cancer was one of the most frequent causes of death, but only in recent years have data been available to prove the frequency of the disease and its high place in the mortality of the human race.

In a recent paper before the American Gynecological Society, an eminent authority—a statistician of a great insurance company—brought together in the most convincing way the statistical evidence, not only of the frequency of cancer, but of its increasing frequency. From these figures it would seem that at ages over 40 cancer is a greater menace to human life than tuberculosis.

The many agencies which have been working for years to protect the health of the people have undoubtedly increased the probability of a longer life. This, in itself, increases the chances of cancer. During the last few years there have been efforts to educate the medical profession and the public as to the frequency of cancer and as to its greater curability when recognized early and properly treated. The American Medical Association appointed, some years ago, active committees on public health and education, and one of these had a subcommittee whose function it has been to deal with the question of cancer. Other medical associations have also appointed special committees to investigate the problem of the best method of educating the public and the medical profession.

In the spring of this year a number of lay women and men, with the advice and encouragement of members of the medical profession, conceived the idea of a national association for the control of cancer. This association has now been established. Its incorporate name has been selected—the American Society for the Control of Cancer. The word "control" was employed because the world should know that the medical profession has accumulated the facts which will prove that the menace of cancer can be controlled. At the recent meeting of the American Medical Association a resolution was unanimously adopted endorsing the organization and objects of the American Association for the Control of Cancer. There seems little doubt that every medical society will do likewise.

This beginning is but a small part of the great and difficult work before the new association. At present the facts well established in regard to cancer are not known by the people or even by the great body of the medical profession. They must be presented in such a way that there shall be no doubt in regard to their authenticity and truth. The conclusions must be those agreed on by the great majority of those who have for years studied the problem of cancer and accumulated this evidence. The truth must be presented to the people in such a way that it will not create fear, but confidence. The message to the medical profession will be equally difficult. The diagnosis of cancer in its earliest stages, when treatment gives the best results, is more uncertain, and the treatment in this stage, although less dangerous, is a more delicate surgical procedure.

Less thought has been given to the practical treatment of the cancer problem than to any other of the great problems of public health. Few have known of the great menace of cancer, as compared with tuberculosis and typhoid fever, or of the number of cures of cancer in its later stages. Fewer have known of the tremendous possibilities of increasing the number of cures when cancer is recognized and properly treated in its earliest stages. Evidence seems to prove that the control of cancer is simply a problem of education.

24 *Wassermann Test. F. Baumann, Chicago.

24. **Wassermann Test.**—The Wassermann test, Baumann asserts, is not a specific reaction for syphilis, but on account of the mildness of the invader it shows up stronger in syphilis than in any other disease. But every disease that causes the appearance of disease products in the blood of the patient will for the time being also give some degree of Wassermann reaction. Experiments which he has been making force him to the conclusion that this test is, furthermore, mainly a group reaction, a non-specific group reaction, and that it is in exceptional cases only that we shall be permitted to exclude any of the factors aiding in the shaping of the final results of this reaction. One factor of the group, namely, the native antisheep "amboceptor," can be excluded from influencing the final result of the test by using an antihuman instead of an antisheep hemolytic system. A number of investigators are advocating such a change of the indicator. The amount of native antisheep amboceptor varies in different individuals, according to their surroundings, and in the same individual according to his general state of health. Syphilis as well as other diseases that depress the state of health for any length of time depresses the amount of native amboceptor. By using an antihuman hemolytic system as an indicator, there is eliminated, therefore, a symptom that may occur in other diseases, but at the same time there is excluded a symptom that does occur in syphilis. The substitution, therefore, of an antihuman indicator for an antisheep indicator deprives the test of a good deal of its sensitiveness. Comparative work with these two hemolytic indicators convinces Baumann that the exclusion of the antisheep amboceptor is desirable and helpful in arriving at a valuable clinical result only in exceptional cases.

25. **Multiple Carcinoma of Skin.**—Loeb and Sweek come to the following conclusions: The formation of multiple carcinoma of the skin depends on a primary increase in activity of certain parts of the epidermis. It is an affection of the epithelial cells independent of proliferative changes or of collections of round cells in the connective tissue, and independent of attractive influences of blood-vessels. The proliferative energy of the epithelium which leads to the formation of the multiple carcinoma is relatively small. The infiltrative power of the proliferating epithelium is equally slight. In consequence of this slight infiltrative power there may be an outgrowth of epithelium into the air instead of a downgrowth into the underlying cutis. In a certain relationship to the deficiency in proliferative and infiltrative power stands perhaps the inability of the proliferating epithelium to undergo the normal metamorphosis of the surface epithelium into keratohyalin and into keratin. As to the cause for the multiple proliferation of epithelium over a certain area of the skin, no definite statement is made by the authors. They say that we may have to deal with a primary stimulation of the epithelium. It is, however, also thinkable, that the pathologic changes found in the skin, especially in the connective tissue, may have entailed an abnormal metabolism of the skin leading to the production of substances exerting a stimulating effect on the proliferative energy of the epithelium at various places. It is furthermore conceivable that in addition slight external stimuli of a more accidental character, as for instance mechanical pressure, the influence of light, Roentgen rays or changes in temperature, may, in such a prepared soil, decide why certain parts of the diseased area become affected and show a proliferation of the epithelium at a time when in neighboring parts the epithelium is still in a resting condition. This suggestion is, of course, of a purely hypothetical character at present. On the other hand, it is not very probable that the changes in the connective tissue which were found led to a decrease in the mechanical tension, under which the epithelium lives normally. On the contrary they notice that the connective tissue resists very successfully at various places the increased tendency of the epithelium to grow downward.

26. **Anaphylaxis.**—Weil believes that guinea-pigs may be sensitized to a foreign protein (sheep-serum or rabbit-serum) by the repeated injection, on successive days, of massive doses (3 c.c.) of the foreign protein. The guinea-pigs become hypersensitive approximately eight days after the last dose. They differ in no essential particular from guinea-pigs sensitized in the usual fashion by a single small dose. The minimal lethal dose in guinea-pigs prepared by a series of injections is found to be larger than in those prepared in the usual fashion. This is attributed to the fact that their blood is very much richer in immune bodies, as is herein experimentally demonstrated. These experiments are offered as further evidence of the view that anaphylaxis and immunity are conditions which differ from each other only in the relative quantity of circulating antibody.

By means of preliminary treatment with normal rabbit-serum a guinea-pig becomes altered in such wise that it is refractory to sensitization by immune rabbit-serum. The effectiveness of this preliminary treatment depends on two factors: the amount of normal rabbit-serum administered, and the length of the interval between the preliminary and the sensitizing injections. The time during which passive sensitization persists, after having been induced by heterologous immune serum, may be shortened by the preliminary, or subsequent, injection of normal heterologous serum of the same species. The preliminary injection of sheep-serum protects guinea-pigs, in a certain proportion of cases, against the sensitizing effect of immune rabbit-serum. This effect is much less regular and pronounced than when rabbit-serum has been used for the preliminary injection. For these facts the following conclusions are drawn by Weil: First, that protection against sensitization, as before described, is due to immunization of the guinea-pig, with neutralization of the antibodies contained in the immune serum subsequently introduced. Second, that it is therefore possible to induce immunity toward specific heterologous antibodies by means of the injection of a normal heterologous serum. Third, that this immune reaction occurs earlier than does anaphylaxis, and that it is also more delicate, in that it indicates the presence of a group reaction, or immunization, which is not revealed by the latter method. Fourth, that the duration of passive sensitization, when induced by the injection of heterologous immune serum, is in all probability determined by the time necessary for the development of an immunity to the introduced foreign serum.

By the injection on several successive days of large doses of normal rabbit-serum it is regularly possible to protect guinea-pigs against the sensitizing action of immune rabbit-serum. This protection may be manifest within one or two days after the preliminary treatment has ended, and continues for at least two weeks longer. After sensitization of the guinea-pig by means of the injection of immune rabbit-serum has been established, it is possible to terminate this before its normal time of disappearance, by means of the injection on several successive days, of large doses of normal rabbit-serum. It is regularly possible to protect guinea-pigs by the repeated injection of large doses of normal sheep-serum against the sensitizing effect of immune rabbit-serum. Sensitization by immune rabbit-serum may be abolished as in two, by the subsequent injection of sheep-serum in repeated large doses. The conclusion is drawn that these phenomena, provisionally described as "saturation" and as "displacement," are probably due to the immunization of the guinea-pig, either directly (by rabbit-serum) or indirectly (by sheep-serum) against the immune rabbit-serum. This view is supported by the conclusions drawn from the two earlier studies included in this paper. Animals actively sensitized against horse-serum cannot be desensitized by repeated injections of sheep-serum. Passive sensitization by homologous immune serum in guinea-pigs has not been prevented by previous treatment with sheep-serum or guinea-pig-serum. Weil believes that these results confirm the view that the phenomena of saturation and displacement are to be explained on the basis of immunization against introduced heterologous antibodies.

27. **Complement Content of Blood.**—The hemolytic complement content of the blood-serum in different varieties and stages of human cancer in the majority of cases was found to be relatively constant by Ordway and Kellert. The amount is practically the same as that found in health and in persons suffering with certain other diseases. Such human serum (in most cases) contains one-tenth to one-twentieth as much hemolytic complement as pooled serum from adult guinea-pigs. There is no increase of hemolytic complement in myelogenous or lymphatic leukemia. The hemolytic complement content in the plasma of citrated human blood does not differ from that in the serum.

28. **Production and Growth of Tumor Metastases.**—The course of procedure to which the patient is frequently subjected—the palpation of the mass in question in repeated physical examinations, the violent scrubbing often employed in preparing the field of operation—is almost identical with that which Tyzzer employed for the experimental production of metastasis. He emphasizes that it would be of advantage to the patient if each questionable tumor of the breast, for example, could be regarded as a high explosive, the least manipulation of which should be absolutely avoided both prior to and during the operation. It is not improbable that by this means metastasis and extension beyond the field of operation could be prevented and the percentage of cases cured by operation increased. From the point of view of metastasis it would appear from Tyzzer's results much less serious to cut into a tumor than to exert pressure on it, although the effect of the distribution of tumor tissue throughout an extensive operation is quite generally understood. It is not improbable that the removal of a tumor of large size from which metastasis has alrady occurred results in a more rapid growth of the secondary deposits. This should not weigh too heavily, however, in considering palliative operations of this sort, for internal tumors not being under the direct observation of the patient furnish a less constant source of apprehension, and the removal of a large external tumor may make the case much easier for the physician to manage.

Operations incomplete but involving the incision of implanted tumors do not increase the incidence of metastases, but these grow more rapidly as the result either of an increase in the amount of food material made available by the removal of a large mass of tumor tissue elsewhere (athrepsia) or of the elimination of the element of cachexia and improvement of the physical condition which almost invariably occurs. Radical operations involving the removal of all the tumor—except minute masses which subsequently come into evidence along the path of the inoculating trochar—if performed just prior to the period in which metastasis commences, results in a temporary freedom from this complication even though recurrence commonly occurs. Metastasis may be artificially produced by the manipulation and massage of the implanted tumor. This is accomplished as readily during the early development of the tumor as in the period in which metastasis naturally occurs.

The production of metastases is dependent on certain demonstrable factors—the biologic character of the tumor, the duration of its growth, the size of the primary mass, possibly peculiar conditions furnished by the host tissues, and, under artificial conditions, forcible manipulation. The so-called "pre-metastatic period" is better accounted for by an absence of the conditions necessary for the dissemination of tumor cells than by a phase of "active resistance" during which the further development of tumor emboli is prevented. By the early artificial dissemination of tumor cells by the manipulation of the primary tumor, this period may be greatly shortened.

29. **Protein Metabolism in Rats.**—The protein metabolism of certain tumor-bearing rats as indicated by the examination of the urine by Ordway and Morris differed from normal controls in regard to elimination of uric acid, which is markedly increased, especially when the tumor is growing rapidly. There is also a distinct increase in creatin and a diminution in creatinin in these tumor-bearing animals.

31. **Complement Fixation in Syphilis.**—Serums of normal persons and normal rabbits as well as serums of persons suffering with diseases other than syphilis and yielding negative Wassermann reactions, the authors found do not contain substances capable of fixing complement with *pallida* antigens. About 50 per cent. of serums from persons in all stages of syphilis and giving positive Wassermann reactions and luetic histories reacted negatively with *pallida* antigens. Two cases of primary syphilis were negative; of twenty-three cases of secondary syphilis, 30 per cent. reacted positively: of fifty-eight cases of tertiary syphilis, 48 per cent. were positive, as were two of three cases of hereditary syphilis. In every instance the degree of fixation with the *pallida* antigen was much less than with the stock lipoidal extracts and in only one case of secondary syphilis treated with mercury was the reaction positive with the *pallida* and negative with the stock antigens. The reaction with the *pallida* antigens are weak and too inconstant to be of routine practical value. Serums of rabbits immunized with pure cultures of *Spirochaeta pallida* yielded strong reactions with the *pallida* antigens. As controlled by the examination of one hundred normal rabbits these serums also gave positive reactions with stock lipoidal extracts.

Many of the human serums and all the rabbit immune serums were likewise tested with control antigens of sterile culture mediums, pure washed cultures of typhoid and cholera bacteria as well as cultures of these organisms in the same culture mediums as used in the cultivation of *Spirochaeta pallida*. With the human serums a few doubtful reactions were obtained with the antigens of sterile mediums and more marked reactions with the typhoid and cholera culture medium antigens. The rabbit immune serums not only reacted strongly with these antigens but likewise yielded weak reactions with antigens of washed typhoid and cholera bacteria. From the fact that a lipoid was demonstrated in these antigens it may be that the non-specific reactions were due to the usual union of lipoid and lipoidophilic antibody, although the authors are unable to explain at present why this is especially true with the rabbit-immune serums. From the fact that the reactions with alcoholic extracts of pure washed spirochetes were uniformly negative it is apparent that the antigenic principle of the spirochete is not readily abstractable in alcohol, the aqueous extracts being preferable in complement fixation reactions.

32. **Wassermann Reaction with Rabbit Serum.**—In these experiments a percentage of serums of normal rabbits yielded positive complement fixation reactions with lipoidal extracts. With aqueous and alcoholic extracts of *pallida* as antigen fixation did not occur. With acetone extracts of syphilitic liver no fixation was found when using 0.05 and 0.1 c.c. of serum; with 0.2 c.c. serum fixation occurs in 10 per cent., and with 0.4 c.c. in 31.3 per cent. of normal rabbit-serums.

With alcoholic extracts of syphilitic liver fixation did not occur with 0.05 c.c. serum; when using 0.1 c.c. fixation occurred in 13.3 per cent.; with 0.2 c.c. in 20 per cent.; and with 0.4 in 27.5 per cent. of normal serums. With extracts of the acetone insoluble lipoid fraction fixation did not occur with 0.05 and 0.1 c.c. of serum; with 0.2 c.c. fixation occurred in 33.1 per cent., and with 0.4 c.c. in 55.7 per cent. of normal rabbit serums. An alcoholic extract of beef heart reenforced with cholesterin showed the highest percentage of positive reactions. With 0.05 c.c. serum fixation did not occur; with 0.1 c.c. fixation occurred in 20 per cent.; with 0.2 c.c. in 40 per cent., and with 0.4 c.c. in 50.8 per cent. of normal rabbit serums. The occurrence of positive complement-fixation reactions with normal rabbit serums and lipoidal extracts bears no relation to coccidiosis. While the cause of this phenomenon is as yet unexplained it is probably due to the presence in rabbit-serum of a lipoidophilic substance with affinity for certain lipoids or lipoidal substances.

34. **Control of Infectious Diseases.**—Hiss outlines briefly the result of the treatment of infections in animals with leukocyte extracts. These infections or poisonings have usually been brought about by intravenous inoculations, and, as a rule, the treatments with extract have been injected subcutaneously, although at times intraperitoneally. Animals receiving subcutaneous injections of rapidly fatal doses of *Staphylococcus pyogenes aureus* can generally be saved by treatment with the extract of normal leukocytes of rabbits even in small doses, especially when these are given intraperitoneally. When intravenous injections of staphylococcus are practiced, the results are different, but treated animals usually survive the controls many days and present modified histologic pictures. In streptococcus infections there was a marked lengthening of life and even a survival of the treated animals, and better results in the animals treated early than in those treated late. All of the animals which lived long enough developed articular or periarticular lesions. Pneumococcus infections surely fatal in untreated rabbits, become significantly modified in treated animals, even if this treatment be delayed many hours. In typhoid infections the animals receiving protection with leukocyte extract, shortly after this treatment, usually seemed worse than the control, and to the inexperienced would appear the most likely to die. But leukocyte extracts have a remarkably beneficial modifying action on the course of typhoid infections or poisonings in rabbits. Severe tests and experiments with meningococcus infection point strongly to the value of leukocyte extract in the treatment of this infection.

The points which Hiss says speak most strongly for the explanation of the beneficial action of leukocyte extracts, as either poison-neutralizing or poison-prohibiting, rather than primarily bactericidal or bacteriolytic, or even one of the immediate phagocytosis, are first, the effect on temperature; for, when the temperature is high it tends to be lowered, and when it is falling below normal from the intensity of the poisoning it tends to rise on treatment; which is a sign, of course, under this condition, of returning strength on the part of an animal; and secondly, the effect in preventing diarrhea, which is a symptom of poisoning in such intoxications.

43. **Danger from Bone Filings.**—January 23, the humerus of Farr's patient was plated after two unsuccessful attempts at reduction, with the patient under ether, had been made. During this operation no special precautions were taken to prevent the "bone dust" from being scattered over the exposed muscles while the bone ends were being sawed off in preparation for the plating. When the second operation was performed for the purpose of liberating the musculospiral nerve from the callus, the Lane plate which was placed on the bone was found completely buried in callus to the depth of 1 cm. The brachialis anticus and triceps, contiguous to the bone, were infiltrated with new bony tissue over an area measuring approximately five inches in length. Farr believes that this condition was evidently due to the scattering of osteogenetic elements over the exposed muscles at the time of operation, as only the portions of the muscles exposed at operation were involved. The overgrowth of bone and the bone plate were removed, and a strip of the triceps was wound about the humerus. A small amount of motion still remained. Great care was used in liberating the musculospiral nerve, which was first identified at the lower angle of the wound.

44. **Sounding-Board in Diagnosis of Diseases of Chest.**—The sounding-board used by Engstad is three feet wide by five feet high, made from two piano sounding-boards, the boards being set four inches apart in a hardwood frame properly fastened with glue and avoiding nails or other metallic reinforcements. The boards are braced in their center by a bridge of hardwood, and the front board has two holes two inches in diameter bored through it, which tends to equalize the pressure of the air between the boards and frame while in a state of vibration and the circumambient air, which is the cardinal principle for the proper reflection and reinforcement of the air-waves, or energy in the form of vibrations.

This apparatus, Engstad says, will markedly intensify all sounds from the chest-walls, and it has been of great service to him in suspected small cavities, deposits and small infarcts in the chest which are revealed by the reinforced vibrations as reflected from the sounding-board, which prevents the sound waves from disappearing in space, but are reflected redoubled in the angle of the impact.

65 *Treatment of Acute Lobar Pneumonia. P. Marvel, Atlantic City.

61. **Pneumonia in Infancy and Childhood.**—The treatment of pneumonia in children, Bell says, should be simple but carefully and individually directed, and laid out under the following four heads: 1. Medical (a) Cathartics.—Bell finds it generally a good plan to empty the intestine with either castor oil, calomel with milk of magnesia or podophyllin and soda. (b) Sedatives.—Sedatives are serviceable for pain and harassing cough. Paregoric is specially suitable for this purpose; codein and heroin may be used, the less of either the better. (c) Stimulants.—When stimulants are necessary Bell uses caffein for the low muttering delirious cases. Alcohol freely even in babies, and in a serious crisis digalen intravenously. Following Sajous' suggestion, he has used in a few cases 5 c.c. doses of normal salt solution every two hours, adding orange juice and egg white occasionally. (d) Serum therapy.—He has used anti-pneumococcus serum in two cases. In one of these antistreptococcic serum was used in conjunction, because streptococci were abundant in the sputum. Large doses were given and the patient did well. It follows that the earlier the serum is given the better the opportunity for favorable action. 2. Hydrotherapeutic.—Sponge baths of water at 21 C., 32 C. or 41 C. (70-90-106 F.). Bell usually begins with temperature 32 C. (90 F.) to 40 C. (104 F.). 3. Dietetic.—The diet must be selected in accordance with age and needs of the child. 4. Hygienic.—Bell has found it advantageous to treat all his pneumonias more or less in the open air.

65. **Treatment of Acute Lobar Pneumonia.**—The treatment which in Marvel's opinion promises most for the reduction in the mortality of pneumonia must be along the line of antipneumococcic serum. It has already been found that an antipneumococcic serum prepared by immunizing dogs with increasing doses of pneumococci obtained by lung puncture in cases of pneumonia will protect mice from a fatal outcome when inoculated with the same pneumococcus in sufficient dose to cause death in control animals, and various serums have been and are now being tried with some degree of success, but limited no doubt by the fact that there are so many different strains of pneumococci that it has seemed impossible to produce a serum that would be helpful in all cases, and there is, of course, no time to produce a serum in each case from the infecting organism.

8 *Some Aspects of Internal Secretion in Disease. G. R. Murray.
9 *Gifts of Surgery to Medicine. B. Moynihan.

8. **Internal Secretion in Disease.**—Murray points out that as yet we are able to recognize with certainty only the maladies which are due to well-marked changes in the structure and function of these organs. He suggests that it is probable that some less definite forms of ill-health may also be due to variations in the activity of one or more glands, the significance of which we shall be better able to appreciate when our knowledge of their functions becomes more exact. What, however, is most desired is to find satisfactory means by which we can supplement deficient secretion on the one hand and control harmful overactivity on the other. He hints that in the light of further knowledge it may be possible adequately to supplement suprarenal insufficiency and so relieve the symptoms of Addison's disease. The treatment of exophthalmic goiter and acromegaly will become more satisfactory as more adequate methods of checking the abnormal flow of secretion are acquired, when it is to be hoped that surgical measures will become unnecessary. Pancreatic diabetes may also prove to be more amenable to treatment by

methods at present beyond our reach. Clinical medicine has already gained enormously from results obtained by experimental pathology, and Murray looks to the future with confidence for efficient methods of treatment within our reach.

In commenting on thyroidal insufficiency, he bids us note that whereas typical cases of established myxedema are strikingly characteristic, *the slight and early forms* of the disease may easily be overlooked. In middle-aged women who complain of lassitude, chilliness and other subjective sensations, associated with slight dryness of the skin, some loss of hair, and a little thickening of the subcutaneous tissues, or other signs of slight thyroidal insufficiency, it is necessary to remember that myxedema may be the explanation of the symptoms, though every one of them, taken separately, is so common and so trivial. He summarizes briefly the effects of the partial or complete failure of thyroidal hormones as demonstrated by the effects of disease or removal of the gland in man and animals, and includes a short historical review of the application of the knowledge so obtained to the treatment of thyroidal insufficiency, making a very modest reference to his own important share in this notable therapeutic advance. The first patient with myxedema which Murray treated is still alive and well, having been kept in health twenty-two years by this treatment, during which time she has taken liquid thyroid extract to an amount which in all is less than one gallon. The use of thyroid extract in various conditions in which there is no definite evidence of any deficiency in the thyroidal hormones makes another interesting section of the address, and the effects of hyperactivity of the thyroid gland, more especially as evidenced in the various degrees of exophthalmic goiter, are of the real importance which he attributes to them.

Murray points out some interesting associations of this disease, notably its relation to sugar tolerance and diabetes and to tuberculosis. He has found that pulmonary tuberculosis occurs but rarely in uncomplicated cases of exophthalmic goiter, and that when it does occur it is usually limited in extent and activity. This apparent resistance to infection he suggests is probably due to the increased activity of the metabolism of the tissues rather than to any direct action of the thyroid secretion. In commenting on the variability of the symptoms of Graves' disease, the occurrence of general and local crises was described by Murray. In the general crises almost all symptoms are aggravated, and the attacks may be alarming and dangerous. The explanation offered is that they are due to a sudden increase in the activity of the thyroid. The local crises may be described as cardiac, cutaneous, bronchial, gastric or intestinal, according to the organ or system mainly affected. To account for these local manifestations it is suggested that the thyroid secretion may contain different hormones capable of activating different organs. In reviewing the treatment of the condition of hyperthyroidism he speaks favorably of the application of suitable doses of Roentgen rays to the gland, and finds that the cutaneous and bronchial crises are generally controlled by belladonna in full doses and the gastric and intestinal crises by opium.

9. **Gifts of Surgery to Medicine.**—Moynihan points out that medicine in its quest of knowledge may rightly levy a tribute from every other science with which it comes into contact. Its doctrines and its practice are tested and may receive support or be refuted by work accomplished in other fields. Surgery in recent years has proved a powerful helpmeet not only in the elucidation of problems of internal medicine, but also by reason of the light it has brought to bear on the functions of many of the organs in the body. The experimental method, as a mode of inquiry, is not excelled in value by any other, and no experiments, Moynihan holds, can claim an equal rank with those which are a part of almost all surgical procedures. The chief glory of the surgeon comes from the dedication of his powers to the service of an individual; but there is a cause also to be served. In every operation something may be learned, not only of those disorders which call urgently for relief, but of other associated, or it may be separate, conditions which chance at the same moment to be present. The researches so carried out on a human patient are performed with a sterner sense of responsibility and with a graver ritual and are impressed by more relevant influences than attach to any other form of inquiry. Their results are accordingly of far higher value. Clinical research, when sedulously conducted and illuminated by the disclosures made on the operating-table, affords the most accurate of all methods of investigation into the diseases by which man is attacked. The succor of an individual should mean also the taking of a step forward in the solution or the better understanding of the manifold and perplexing problems of disease.

16 *Ligation of Internal Iliac and Ovarian Arteries for Inoperable Carcinoma of Uterus, Combined with Curettage and Cautery. V. B. Green-Armytage.

11. **Estimation of Chlorids in Blood.**—The method used by Overbeck-Wright is based on the principle of diffusion. All that is required is a couple of dozen glass tubes of the diameter of a goose-quill, about 6 inches long and sealed at one end; a small wooden stand, like a test-tube stand, for holding the tubes; a vernier scale into which the tubes are clipped for the necessary readings to be made, and a Wright's pipet. Reagent: (a) Constituents: agar-agar (pulv.) 6 grains; silver chromate, 1 grain; glycerol (glycerin) ½ ounce; distilled water, 2 ounces. (b) *Preparation:* Mix the agar-agar and silver chromate thoroughly in a mortar, emulsify with the glycerol and then add the water, mixing carefully throughout. Transfer to a porcelain crucible and bring to the boil over a spirit lamp. Boil for five minutes and then fill into tubes. Allow it to set. Place 5 mm. (¼ inch) depth of the solution to be tested on the top of the jelly in one of the tubes and into eight other tubes fill in respectively 5 mm. (¼ inch) of salt solutions varying from 0.8 to 0.1 per cent., stand for fifteen minutes and then read off the depth of penetration into the jelly as shown by the decolorization, the rich pink of the silver chromate becoming a flaky white with chlorids. A comparison of the depth of penetration of the solution to be tested with that of the varying salt solutions gives one at once the percentage solution of chlorids. So far Overbeck-Wright has found that normal blood contains a 0.5 to 0.75 per cent. solution of chlorids in the plasma, and he dilutes the blood as a rule to 1 : 3, as he finds that a larger variation in the smaller percentages and less chance of error. A 6 per cent. solution of sodium citrate or a 3 per cent. solution of sodium oxalate may be used to prevent coagulation, but the latter is preferable. No more blood is required for this test than for a Widal's reaction and a mere prick of the finger as a rule gives ample amount for the test.

16. **Ligature of Iliac and Ovarian Arteries.**—Green-Armytage calls attention to an operation first suggested by Charles Ryall of the London Cancer Hospital, namely, tying of the internal iliac and ovarian arteries, the principle of the treatment being vascular starvation of the growth, and being based on the same principle as the occasional operation of ligation of the external carotids for the terrible sufferings of advanced cancer of the tongue. In the Eden Hospital, at Calcutta, when the cachexia and general condition of the patient prohibit laparotomy, it is the custom to use the sharp spoon thoroughly and afterward go over the bleeding surface with Paquelin's cautery, and then plug the cavity with tampons which have been soaked in a saturated solution of zinc chlorid and dried the vagina below being plugged with powdered soda and gauze. In three to five days the plugging is removed, and vagina douched daily until the sloughs separate. When, however, the patient's general condition is fair, pain is a marked symptom, or hemorrhage is severe, they have per-

formed Ryall's operation. During the last eighteen months nine patients have been operated on. At the end of the operation if the pulse is good. the patient is put in the lithotomy position, and the growth is dealt with as detailed above. If the patient's condition is not good, the growth is not dealt with till a week or ten days after the primary operation. There is usually a slight febrile reaction after the operation for a few days which Green-Armytage says need cause no alarm. The after results of the operation are astonishingly good.

The general health improves markedly, the pain subsides entirely, as the discharge ceases, and the growth of the cancer is retarded for a considerable time. The net result is that, though the days of the patient may not have been greatly extended, she is able to live in comparative comfort for a very much longer period than the usual lines of treatment permit. Three cases have been seen 7, 9, and 13 months after operation, comparatively well and with no symptoms beyond a discharge due to a slow recrudescence of the original tumor. In four cases in which vesical irritability was a marked feature of the disease, this symptom completely disappeared for many months. There has been no operation mortality.

23 Decalcifying Action of Oxalic Acid. H. J. B. Fry.

20. **Contamination of Thoracic Cavity.**—The inoculation of a certain quantity of oil into the peritoneal cavity to prevent any absorption of septic material has been recommended and has been practiced fairly extensively, especially by continental surgeons. A few experiments bearing on this question were also performed, oil being inoculated from fifteen minutes to twenty-four hours before the injection of the bacilli. Although the number of experiments in this direction have not been numerous, Twort says, they demonstrate clearly that the oil does not prevent the escape of bacteria from the peritoneal cavity and their absorption by the thoracic glands, and it is doubtful if it in any way hinders the dissemination of the bacilli. The time necessary for the escape of infectious material from the peritoneal cavity is thus often only a question of minutes, and it is obvious that even during an operation if the general peritoneal cavity is accidentally contaminated from the rupture of a localized abscess, etc., ample time is given before the end of the operation for the thoracic glands to become infected, and if these glands are penetrated there is a danger of the infection becoming generalized. These facts may explain the beneficial effect of Fowler's position after abdominal operations.

26 Primary and Epileptic Dementia in Children. C. Perin.
27 Meningococcus Septicemia. S. Portret.
28 *Infectious Endocarditis in Children: Three Cases. A. Blind.

25. **Effusion in the Pericardium.**—Blechmann insists that this is a more frequent occurrence in children than is generally recognized. It is not exceptional even in young infants, and fully 25 per cent. of all cases of pericarditis, he affirms, occur before the age of 5, and 50 per cent. before 15. These percentages are based on a study of 500 cases of pericarditis in the London hospitals. Effusion in the pericardium is rarely demonstrated during life but he found it in 3 per cent. of all cadavers, and there is nothing to justify the assumption that it is an agonal phenomenon as usually believed. In young infants the pericarditis with effusion is generally secondary to bronchopneumonia or empyema; between 5 and 15, acute articular rheumatism is the usual primary cause except that after 10 pneumonia may be incriminated. Between 15 and 30, rheumatism and pneumonia are encountered in the antecedents with about equal frequency, and also eruptive diseases or a bone affection. After 30, nephritis is generally responsible or cancer, and a hemorrhagic effusion is more frequent. The heart enlarges with the onset of pericarditis and dulness appears in the fifth right intercostal space (Rotch's sign). When this is accompanied by a progressively increasing symmetric area of dulness, an effusion in the pericardium is almost beyond question. Signs of abdominal and diaphragm paresis are more common in pericarditis without than with effusion. This alone may point to incipient pericarditis. The dyspnea with a large effusion in the pericardium may be relieved only by assuming the knee-chest position. Permanent distention of the jugular veins, without venous pulsation, shows that there is some obstacle in the pericardium. The "paradoxic pulse" is an important sign of pericarditis with effusion. The heart changes to a more vertical position, the apex abnormally low

The effusion collects below, back of or at the side of the heart but never in front, consequently the puncture had best be made below the xiphoid process, and if an incision is to be made it should be below the left costal arc and cartilage, so that the pericardium can be reached through the epigastrium. This technic is particularly advantageous for children; it spares the pleura, provides direct access to the pericardium and permits drainage at the lowest point. An exploratory puncture is always indicated. If a serous effusion is found of acute infectious, toxic or mechanical origin, the puncture alone is sufficient; in case of a tuberculous process puncture or pericardotomy without drainage is indicated. Purulent effusions require pericardotomy and drainage. The life of the patient may depend on early intervention, and he emphasizes that it is better for it to be too early and too extensive rather than to temporize and be too timid. Exploratory subxiphoid puncture should be the rule on the first suspicion, and this alone may cure; if not, examination of the fluid obtained at the puncture will show whether pericardotomy should follow at once or not.

28. **Endocarditis in Children.**—Blind's three cases were in children of 6 and 8, and the diagnosis was difficult as the causal acute articular rheumatism had passed unnoticed, or had not attracted the attention it deserved. The evolution of the endocarditis is very slow in such cases; the children have to be kept under supervision a long time and frequently examined by auscultation and the thermometer. The latter will reveal slight attacks of intermittent fever testifying that the endocarditis is still at work. The prognosis is difficult, as even mild endocarditis may leave irreparable valvular disease while extremely serious forms may heal without a trace. The salicylates and acetylsalicylic acid (aspirin) should be given not only during the acute phases but during the long drawn out mild evolution, and thus they may have to be kept up for a long time. Blind's three cases were all encountered in one month, suggesting an epidemic character, and all the children were free from symptoms after a few months of treatment.

32 Extraction of Foreign Bodies under Radioscopic Control. P. Mauclaire.

29. **Tropical Liver Abscess.**—Sambuc calls attention to a number of points he has learned from practical experience in French China. As a rule the abscess is secondary to ameba dysentery, but alcohol and opium smoking are important factors. In 103 cases, 1893-1910, only two of the patients were women and only eleven were natives. Dysentery is less preva-

lent among the natives; their food is less harmful for the liver than the diet of Europeans, while they use less alcohol. The primary dysentery may be so mild as to escape detection or it may be mistaken for ordinary diarrhea, but dysentery is recorded as the primary cause of the liver trouble in 70 per cent. of the cases. The abscess was multiple in about 40 per cent., up to four abscesses in twelve cases and number unknown in thirteen. In twenty-two cases the abscess emptied into the air passages (7 with only 2 deaths); pleura (4); intestine (4); peritoneum (2); pericardium (1) or kidney (1), with death in fourteen of the twenty-two cases.

The front upper part of the right lobe is the most frequent seat of the suppuration, a zone corresponding to the seventh, eighth and ninth intercostal spaces. Differentiation of suppuration in the liver is often quite difficult as the liver trouble may simulate pleurisy or pulmonary tuberculosis or appendicitis or may present a syndrome suggesting malaria or typhoid. There do not seem to be any pathognomonic signs; the abscess may occur even without pain or swelling in the liver. The frequent congestion of the liver accompanying dysentery is also misleading. Abscess of the liver should be suspected whenever there is abnormally high evening temperature of uncertain origin. Puncture is harmless and generally permits differentiation of the lesion. The diagnosis of multiple foci is generally impossible except from the course of the affection. In case suppuration in the inferior aspect of the liver is suspected, an exploratory laparotomy is indicated. The abscesses close to the diaphragm are generally missed with an exploratory puncture as this is usually done too low for them. Among the post-operative complications, pleural effusion may prove fatal even when not very profuse.

He gives the details of fifteen especially interesting cases out of his total 202. In one case the liver trouble had been long erroneously treated on the diagnosis of malaria. In another an abscess in the right lobe was followed by one in the left lobe after a year's interval. In another case forty-eight punctures were made in the course of a month before the abscess was finally discovered. In another case the liver contained five liters of clear yellow pus. The absence of fever was noticeable in several of the cases. The bibliography on the subject since 1906 is appended.

30. **Treatment of Echinococcus Disease of the Peritoneum.**—Dévé uses a two-way trocar which permits aspiration of the contents of the cyst and then injection of a 5 or 10 per cent. solution of formaldehyd. If the cyst is pedunculated he cuts it out at once, but if not, and if it is very large, he applies the above technic and later opens the pocket and clears out the membranes, suturing and reducing the sac without draining. If the sac is not larger than an egg, the injection of the formaldehyd is sufficient alone. The surgeon should proceed very cautiously and not try to finish up the whole thing at one sitting.

41 Extreme[illegible] is: Two Cases. Nicolich.

36. **Transfusion of Blood After Serious Hemorrhage from the Urinary Apparatus.**—Legueu gives minute directions for applying Crile's method of direct transfusion, and reports a case in which it was used for a patient of 69 extremely debilitated from traumatic and spontaneous hemorrhage from the bladder. The donor was the healthiest of the patient's three daughters, and the immediate effect was brilliantly successful but the patient succumbed in a few weeks to complications, among them a suppurating eschar. Legueu regards the method as destined to realize actual resurrections in many cases, and urges others to master the technic so as to be ready to apply it properly in emergencies.

37. **Renal Tuberculosis in Girls.**—Oraison knows of only forty-eight cases on record of tuberculosis of the kidney in children, and here adds three to the list. One of the children had Pott's disease, another had had a brother and sister die of tuberculosis. The symptoms were about the same as with adults except that the children all had incontinence of the bladder. One child was apparently cured by nephrectomy; the child with the spinal disease was not operated on. Catheterization of the ureters is possible in children after 6 or 7 and even easy in some; Oraison has applied it to two children of 7 and 10. It is possible, he remarks, that with renal tuberculosis in children medical treatment might be given a little longer trial than in adults, in the very incipient cases. In one of his cases the mother was affronted with his diagnosis of tuberculosis of the kidney in her apparently healthy little daughter, although he found the right kidney large and tender and the terminal urine contained a tinge of blood. A year later nephrectomy became indispensable and the kidney was found studded with cavities. The child still has symptoms on the part of the bladder. The first sign of trouble in this case had been frequent micturition with extremely limpid urine; he regards this "limpid pollakiuria" as an important sign of incipient renal tuberculosis at any age.

38. **Examination of the Blood with Albuminuria.**—Roux declares that examination of the blood is indispensable along with other diagnostic measures in kidney disease. It is even more important than the rest, he insists, in many cases in which the main source of the albuminuria is not in the kidneys but is the result of disturbance in the blood, a dyscrasia of the blood. This may be both a cause and an effect, and it should receive adequate attention in treatment. The system must be toned up without intoxicating it, supplying the needed minerals for renovation of the morbid blood corpuscles. Roux practices at the Saint-Nectaire mineral springs, and has had more than 1,000 albuminuric patients taking the waters, and has found in this discovery of the dyscrasia of the blood the explanation of the remarkable benefit from the waters in certain cases. The blood corpuscles may be remarkably resistant, even more so than normal. These are the cases with abnormally high blood-pressure and signs of fibrous degeneration of the kidneys. The unusually high resisting power of the corpuscles seems to be a defensive reaction on the part of the organism, constantly required by the impaired eliminating power of the kidneys. When this extremely pronounced resisting power of the corpuscles is accompanied by persisting and pronounced retention of nitrogen and chlorids or high albuminuria, the prognosis is very grave. The patients are already in progressive toxemia. On the other hand, when the leukocytes display a much reduced resisting power, and the general health keeps good, the kidneys do not seem to be so seriously affected as in the first group, and the prognosis depends mostly on whether the blood can be brought back to normal. Each exacerbation of the kidney trouble is a new menace, but a clinical cure is still possible although there may be persisting slight residual albuminuria as the glomeruli are left unduly porous. It is easier to act on the blood than on the kidneys, he adds, and the tonic and rejuvenating action of mineral waters in these cases is readily explained by their action on the blood, while it is impossible to explain it if we ascribe the albuminuria solely to the changes in the kidney.

He gives the technic with which he determines the resistance or fragility of the leukocytes, mixing first 1 drop of blood with 30 drops of a mixture of 1.5 gm. sodium chlorid, and 1.2 gm. sodium citrate in 300 c.c. of distilled water. After twenty minutes, 2 drops of formaldehyd diluted with its own volume of distilled water are added; the whole is centrifuged, the deposit still moist is spread on a slide by capillary attraction from the pipet; fixed with alcohol-ether, and stained with hematein for ten minutes and eosin-orange for twenty seconds. The resisting leukocytes are round, the nuclei distinct and separate, while the leukocytes that are below par have irregular outlines, the nuclei look blurred and blend more or less together, and they take the stain poorly

40. **Renal Hematuria after Nephrectomy.**—Peña summarizes twenty-two cases of hematuria coming on soon after removal of the other kidney for tuberculosis. It may be the sign of a tuberculous process in the remaining kidney, too slight to have been detected by the diagnostic measures applied, or it may be the work of some ordinary infection or a manifestation of hematuric nephritis. In any event, the prognosis should always be guarded as the course in his cases of this kind demonstrated that the hematuria could not be ascribed to a mere reaction congestion.

Revue de Chirurgie, Paris

44 *Metastatic Abscess in the Brain. (Abcès métastatiques de l'encéphale en rapport avec les suppurations hépato-pulmonaires.) Couteaud.
45 *Mercuric Chlorid as a Surgical Disinfectant. (Le sublimé en chirurgie.) E. Marquis.
46 Danger from Ligation of Internal Jugular Vein and Resection of the Pneumogastric. (La résection unilatérale de la jugulaire interne et du pneumogastrique est-elle inoffensive?) P. Guibal.

43. **Fracture of the Petrous Bone.**—Nimier advocates the transmastoid route for access to an extradural hematoma complicating fracture of the petrous bone. If the hematoma is intradural and it cannot be removed by repeated lumbar puncture, the best mode of access is through the temporal bone above the mastoid. This opening can be made first or as an extension of the transmastoid operation. In case of infection, repeated lumbar puncture and decompressive trephining aid in protecting against involvement of the brain, especially when an accompanying or pre-existing otitis has been treated properly, without wasting time on alleged "meningism." Some cases are reported in detail to show the danger from neglect to make a thorough examination when the operation is once decided on. One patient with old bilateral otitis was kicked in the head by a horse, and two operations six months and eight months later seemed to relieve the otitis, which had flared up after the accident, but the patient died and necropsy revealed an abscess in the cerebellum which could easily have been evacuated if the meninges had been incised at the operation.

44. **Metastatic Abscess in the Brain with Liver and Lung Abscess.**—Couteaud reports a case from his own practice and summarizes several other unpublished and published cases, bringing the total to fifteen. The left side and the frontal lobe were most frequently involved. In two cases the brain abscess was secondary to fetid bronchiectasia. To date these metastatic abscesses have invariably proved fatal. In case of ameba dysenteric abscess it is possible that administration of emetin might transform conditions in the primary focus so that evacuation of the metastatic abscess might have a chance for success.

45. **Mercuric Chlorid in Surgery.**—Marquis ascribes to Koch the reputation enjoyed by mercuric chlorid as the "sublime antiseptic." He reviews its history and reports experimental and clinical research, the results of which, he says, have pricked the bubble of its reputation and shown it to be the least penetrating of the surgical disinfectants in vogue and, in spite of its great antiseptic power, to be the least bactericidal of all.

47 *Mistakes in the Diagnosis of Appendicitis. F. de Quervain.
48 Hemorrhagic Myeloid Leukemia. H. Ter-Barseguian. To be continued.
49 Gas Embolism during Procedure for Artificial Pneumothorax; Recovery. *Sillig.*

47. **Mistakes in Diagnosis of Appendicitis.**—De Quervain has been examining the records of the different Swiss hospitals during the last five years and has found nearly a hundred cases in which an operation was done on the erroneous diagnosis of appendicitis. In considerably more than half the cases the trouble was some acute surgical abdominal affection which required a laparotomy, so that no harm was done by the operation, but in about twenty cases no operation was actually needed. In seven cases the trouble was really pneumonia; as it commenced with abdominal symptoms it was mistaken for appendicitis. He warns that children are liable to vomit on the slightest excuse, without necessarily having anything the matter with stomach or bowels and they are liable to run up a fever even more readily. Children are also inclined to locate at the umbilicus anything wrong within. The problem is rendered still more difficult by the cases of pneumococcus peritonitis, especially in girls, and liable to follow pneumonia. With older children and adults, the decision to operate is made more readily than for children under 5, while appendicitis is relatively rare under this age. In three cases typhoid fever was mistaken for appendicitis; this is particularly liable to occur when the patient and family give misleading accounts of the antecedents. Whenever the general depression and headache cast doubt on the diagnosis of appendicitis, it is wise to examine the blood for typhoid or paratyphoid bacilli and put away the bistoury. In seven neuropathic cases the patients simulated the symptoms of appendicitis and were needlessly operated on.

He repeats the warning of the English surgeon to be wary in accepting the diagnosis of appendicitis in women when the hymen is not intact. Minor accessory details may suggest the true cause of the disturbances in a spontaneous or criminal abortion: vagueness as to the date of the last menses, and the worried expression of the patient and her fiancé; slight pressure on the breast may cause exudation which clears up the diagnosis at once. In one case a young woman appeared with the diagnosis of appendicitis the day after a ball; her temperature was over 104 F. and face congested. Examination disclosed a staphylococcus peritonitis from recent rupture of a right pyosalpinx. With rupture of a pregnant tube a movable area of dulness develops almost at once, and an effusion can be palpated in the pouch of Douglas, while the tint of the ears, lips and nails shows the anemia. Add to this vagueness as to the last menstruation, and the assumption of appendicitis can be dropped. In conclusion de Quervain says that knowing the dangers of temporizing with true appendicitis, that surgeon is the bravest who does not fear occasionally to run the risk of a false diagnosis.

56 [illegible]. P. Lazarus.
57 [illegible]. H. Reiner.
58 [illegible] Pulsus durus.) B. Lewinsohn.

51. **Gastric and Duodenal Ulcer.**—Sherren has operated for duodenal ulcer in 190 cases and for gastric ulcer in 179, and reviews this material from the standpoint of diagnosis and indications. Remissions in the pains are peculiarly characteristic of chronic gastric or duodenal ulcer. Days or weeks of the attacks of pain coming on regularly at a certain hour after meals may alternate with long periods of apparently normal digestive conditions. There is nothing pathognomonic of hour-glass stomach except possibly the persistence of the symptoms; after years of intermittent dyspepsia, the disturbances gradually become practically continuous. There was no free acid in seven of his nineteen cases of hour-glass stomach and the acidity was subnormal in eleven of the thirteen tested. Only four of the nineteen were men. In only 123 of his 160 cases of chronic duodenal ulcer were the symptoms characteristic; the others suggested gall-stone

trouble or gastric ulcer. Hunger pain was present in all but twenty of 146 cases; in the intervals the patients felt entirely well. Anger, chilling and overwork are liable to bring on an attack. In one group there was absolutely no pain at any time; the symptoms consisted merely of attacks of dilatation of the stomach with vomiting, alternating with intervals of complete health. There was excess of free acid and the total acidity was high; the opposite is the rule in cases with similar symptoms due to gall-stone or coprostasis.

Before any operation on the stomach for a chronic condition he has the mouth carefully supervised and decayed teeth treated; beginning twenty-four hours beforehand only sterilized food is allowed. Afterward the patient is allowed to drink freely. Vomiting is unusual. He impresses on the patient the necessity for care in the diet for three months, avoiding roast beef, ham and bacon, and taking between meals a teaspoonful of a powder containing equal parts of sodium bicarbonate, magnesium carbonate and bismuth oxycarbonate. Hematemesis was the first symptom of trouble in 75 per cent. of the young women patients but it seldom proved fatal. He never operates for this alone, but when there is bleeding from a chronic gastric or duodenal ulcer, this calls for operative measures without delay. He declares that the danger from this tardy and grave complication of a chronic ulcer is not appreciated as it deserves. The hemorrhage may be fulminating; as a rule it stops spontaneously but returns later and proves fatal. The operation should be done as soon as the condition permits, not later than thirty-six or forty-eight hours, keeping the stomach absolutely quiet in the interim.

52. **Vomiting of Pregnancy.**—Asch thinks that the vomiting of pregnancy is readily explainable by various factors which cooperate in its production and which are generally under our control, so that it is possible to ward off serious trouble from this cause. The nausea experienced by some persons in swinging or riding in a merry-go-round is a reflex phenomenon, not a neurosis, and the vomiting of pregnancy is a similar reflex phenomenon. The existence of the pregnancy, the germinating ovum, has a tendency to upset the training of civilization and bring back a reversion to primitive reflexes. Another factor at work is the dread of the burden of responsibility a child brings with it; the pregnancy may be unwelcome, and these psychic factors depress the appetite and upset the digestion. When vomiting has once occurred, it occurs afterward more readily, as a memory process.

Another factor in the loss of appetite, he explains as *Ueberhungertsein*, that is, the loss of appetite which follows when one is overfatigued or does not eat when hungry. After a certain period the sensation of hunger subsides. The pregnant woman needs nourishment for two, but if her hunger is not satisfied at the proper time, she loses her appetite; if then she eats from duty or custom, without appetite, she is liable to neglect proper mastication and the stomach does not do its work properly in turn. As the pregnant woman needs more nourishment than under other conditions, the ordinary intervals between meals are too long for her, and by the time the meal arrives she has lost her appetite owing to the *Ueberhungertsein*. Added to all this is the fact that in our civilization the natural instincts are deadened, the reflexes sluggish in comparison to primitive peoples. Tobacco, for example, usually induces nausea when used for the first time, but not after one has become used to it. A pregnant woman, however, is liable to feel nausea at the smell of tobacco when at other times she may even, herself, enjoy smoking.

The pregnant woman does not realize that she needs more nourishment; her reflexes are deadened by the customs of civilized life, but she should eat oftener than at other times, and experience has shown that she tolerates better meals of either fluid or solid food, not the two combined. Asch therefore orders her to eat at intervals of two and a half hours, alternating fluids and solid food, not drinking at meals with the latter, but drinking copiously at other times. Before going to bed and if she is wakeful at night he orders something light, not requiring much chewing as this is liable to induce wakefulness. If there is nausea when she sits up first in bed in the morning—which he ascribes to anemia of the brain, as in seasickness—he has her take through a tube or otherwise, while still reclining, a glass of milk or cup of coffee, chocolate, tea or soup and lie still for fifteen or twenty minutes afterward. If there is a distaste for anything of the kind, a glass of hot Vichy or other water might inaugurate the custom. In some cases the vomiting comes on for the first time in the morning as the teeth are brushed; in these cases treatment of the accompanying catarrh of the throat will generally put an end to all trouble. The meals can be eaten reclining, and reclining after meals is useful, as also application of heat, a thermophor. In one almost desperate case he tided the patient past the danger period by feeding exclusively with frozen hard milk, coffee, apple sauce, ice cream, etc., all frozen hard.

Great evil is often done by the accounts of the experiences of friends and the advice of relatives, keeping up the memory of vomiting and bringing back the nausea. There is still another group of cases in which the vomiting is a reflex from contracture of the cervix. Dilatation of the os is often followed by relief from all symptoms and the pregnancy persists undisturbed. If this and all else fails, the dilatation can be repeated and Nature left to evacuate the uterus.

53. **Theory of Exophthalmic Goiter.**—Marimon presents arguments to sustain the view that myxedema and exophthalmic goiter are due to the same cause, insufficient thyroid functioning. The former is the result of defective utilization of the iodin assimilated from the food and metabolized in the liver or elsewhere. Exophthalmic goiter, on the other hand, is the result of injury from iodin getting into the blood insufficiently metabolized. This assumption explains the coincidence of myxedema and exophthalmic goiter, which he has frequently observed and which it is impossible to explain by the current theory that myxedema is the result of hypothyroidism and Basedow of hyperfunctioning. As he remarks, a glass cannot be full and empty at the same time.

62. **Acute Mental Disease.**—Weber refers in particular to the psychoses which have a sudden onset and fulminating course with fatal outcome, and describes several cases of this type. In one, a young man of 27, free from syphilis and drinking habits, had several attacks of influenza and as the last attack subsided developed an acute and fatal psychosis. Necropsy in this as in the other cases revealed a combination of several morbid processes none of which alone could explain the acute psychosis, but their superposed action on an old chronic cerebral affection was responsible for the acute mental disease. The cerebral affection although chronic had evidently been so mild that it had caused no functional dis-

turbances, notwithstanding its diffuse character. Only when some acute injury was superposed, as from a trauma, intoxication, infection, or affection of other organs, especially of the cardiovascular system, did the brain break down. The chronic cerebral affection found in the above cases was a diffuse chronic fibrous leptomeningitis or diffuse arteriosclerosis of the cerebral vessels. The latter may be disclosed only by the microscope. The leptomeningitis may date from some infectious disease in childhood; it is possible that a similar combination of several injurious factors may be responsible for other forms of mental disease.

67. **The Hemorenal Index as Test of Kidney Functioning.**—Bromberg gives an illustrated description of his apparatus to determine the relative electric conductibility of the blood and urine as a means of demonstrating their content in inorganic salts. In health the ratio of concentration in the urine and blood is as 2 to 1. If the ratio is 1.5 or less with bladder urine, both kidneys are probably diseased; if the urine from the ureter catheter on the sound side shows a ratio of 2 or even 1.8, the diseased kidney can be removed without hesitation. The amount of resistance offered by the fluid under examination to the electric current is the principle on which the test is based; only 0.5 c.c. of urine and 0.5 c.c. of blood serum are needed for the comparative test. He says that the instrument described enables the test to be applied in the easiest and simplest manner and that the findings are more reliable than with any other technic.

68. **Syphilis and Neurasthenia.**—Krebs is convinced that the causal agent of syphilis is responsible not only for the tardy anatomic injury of the central nervous system manifested in paralysis and tabes, but that it is also directly responsible for the neurasthenia which he found marked in 43 per cent. of his 114 syphilitic patients with neurasthenia or other functional nervous affection. On the other hand, only 18 per cent. of 1,000 patients in other categories had symptoms of neurasthenia. The practical conclusion follows that the Wassermann test should be applied to all neurasthenic patients when there can be the slightest suspicion of syphilis; in case of a negative response, he advises to test the cerebrospinal fluid. If the reaction is positive, antisyphilitic treatment should be instituted in combination with general tonic measures and measures addressed to the nervous system. He thinks that syphilitics should take a regular four-weeks' course of treatment every year even when they are free from symptoms, and more when symptoms develop. Repetition of the Wassermann test is not so imperative.

71. **The Children of the Tuberculous.**—Weinberg has records of 5,000 families with one or more tuberculous members and a total of 18.000 children whose history is known until their twentieth year. This material is analyzed from various standpoints; it confirms the special danger of contact infection.

84. **Retroflexion of the Uterus.**—Franqué insists that retroflexion does not need correction unless it is causing symptoms, as a rule; indiscriminate treatment in every case, even in virgins, may do great harm. The wearing of a pessary is liable to bring on catarrhal conditions and often entails posterior parametritis and pelveoperitonitis. He knows of one physician who systematically corrects retroflexion by vaginofixation or ventrofixation; he could write a book on the later disturbances in childbed resulting from his hundreds of such operations. Many of the patients afterward came into Franqué's service, still complaining of their old trouble or with new ones superposed. Even the Alexander-Adams operation does not always correct the trouble and, if it does, does not always cure the disturbances because the retroflexion was not responsible for them in the first place. Examination of women long after treatment for retroflexion shows that they are rarely cured of their old troubles, while systematic abstention from any treatment in a series of cases will show that the women do equally well without any local measures. The exceptional cases in which treatment is justified are the rare instances of traumatic dislocation of the uterus with an inflammatory reaction. Here the uterus must be restored to normal place on account of the danger of its becoming bound down by adhesions.

Franqué emphasizes that the normal retroflexed uterus is unable to exert pressure on the rectum or the sciatic plexus as it is too small; trouble is liable only when there is inflammation or when the uterus is enlarged from chronic metritis, tumors or pregnancy. Even the pregnant uterus presses only on the bladder and urethra, as a rule; if the retroflexion of the gravid uterus is discovered before serious symptoms have resulted, it is sufficient to straighten it and, up to the fourth month, introduce a pessary, if this can be done with ease. If not, the uterus may gravitate into normal place if the woman assumes the knee-elbow position or the lateral-abdominal position with the pelvis raised. If this fails, the elastic pressure of a colpeurynter in the vagina will generally answer the purpose. Of course acute symptoms on the part of the bladder call for more active measures, emptying the bladder, straightening the uterus and introducing a pessary, under general anesthesia at need. Retroflexion discovered during the puerperium should also always be corrected and can generally be cured by wearing a pessary for six months to a year. The displacement in these cases may first reveal itself by hemorrhage in the second up to the sixth week after delivery. These hemorrhages stop at once when the uterus is straightened, and ergot and hot vaginal douches are given. Other conditions generally demanding treatment are when with the retroflexion there is prolapse, sterility or habitual abortion. Nervous dyspepsia and gastric symptoms in general he does not regard as indications alone for correction of retroflexion. It is best not to call the patient's attention to her retroflexion. Dysmenorrhea likewise is scarcely ever the direct consequence of uncomplicated retroflexion.

85. **Acute Infections in Infants.**—Müller remarks that the lime-light of attention has shifted in the last few years from the difficulties of infant feeding to the dangers of acute infections for infants. Many of the old febrile "digestive disturbances" are now known to be the work of infection. Some of the known air-borne infections manifest themselves mostly by intestinal symptoms. The purely intestinal affections of infants have constantly lost ground, while among the parenteral, infection by way of the air is becoming more and more important as infection by contact grows less frequent.

The complex of infections which we call influenza is particularly noxious for infants; the influenza may manifest itself with a catarrhal fever and inflammation in the air passages; or it may induce predominantly intestinal symptoms, or the syndrome may be merely an intermittent fever without other symptoms but suggesting a septic course, probably due to general toxemia. Influenza is air-borne, as a rule, and partitions a little over six feet high seem ample protection. Glass "boxes" of this kind to isolate the infants have answered the purpose of protecting against all these air-borne infections except chicken-pox; the germ of this seems to be so light that it does not settle down in the quiet air of the "box" but floats off over the partitions. Meyer has recently reported that children suffering from recurring influenza suddenly began to thrive when they were placed in "boxes."

Another evil of influenza is its frequent connection with diphtheria. In his service, throat diphtheria is very rare in infants but numbers of the little ones are carriers of diphtheria bacilli. In many instances, the "coryza of infants" is really a combination of influenza and diphtheria; the nasal secretion is usually bloody-purulent in these cases. The gravity of such a combination is obvious, and the necessity for bacteriologic examination and antitoxin treatment. The latter seldom cures but at least it prevents the spread of the diphtheria to the throat. Infants seem particularly susceptible to whooping-cough, and the course and effects are exceptionally serious in them, especially in the rachitic. The exudative diathesis predisposes to pertussis, but in his experience the manifestations did not seem to be more severe in the children inclined to spasmophilia than in others. In all cases of acute infection in an infant, the first and main points are to protect it against new infections, to isolate it and to keep it in a sunny room: the sunlight is a particularly powerful disinfectant in respect to influenza.

In conclusion he calls attention to the variation in the character of epidemic infections at different times, and reiterates anew the importance of paying less attention to the intestines of infants and more to their general infections.

86. **Recently Discovered Factors in the Physiology and Pathology of Dietaries.**—Schaumann was one of the pioneers in the research on dietary antineuritic factors, and he here reviews his own and others' work in this line to date. (The Journal has editorially reviewed the outcome from time to time as, for instance, in the issue for May 17, 1913, page 1543.) Schaumann thinks it is a significant fact that the proportion of phosphorus in the brains of pigeons with polyneuritis was found abnormally small. His continued research has confirmed the relatively minute proportion of these antineuritic substances in the food; also that they are present in most articles of diet but are readily removed or destroyed. Rice and other cereals lose them by polishing, and they are destroyed in other articles of food by heating above a certain point or long cooking, by desiccation and by pickling, by boiling in excessively alkaline water, by mouldiness, and possibly by the action of the intestinal flora. The disturbances which result from lack of this protecting substance or substances take different forms in different living beings: A herbivorous mammal develops scorbutus, an omnivorous mammal a mixture of scorbutus and neuritis, while goats, monkeys, fowls and pigeons develop multiple neuritis.

The practical conclusions from all the research reported are that the dietary of man must comprise not only the familiar carbohydrates or fat, protein, mineral elements and water but it must include minute amounts of these still unisolated substances which are of vital importance. It must further contain albumin with a certain amino-acid content, especially tryptophan and tyrosin. The lack of one or more of these still unisolated substances is liable to entail certain single or combined metabolic disturbances. All this throws light on the diseases of deranged metabolism in which he includes rachitis, pellagra, beriberi and scorbutus.

88. **Arteriosclerosis Before Thirty.**—Hofbauer thinks that the reports of cases of arteriosclerosis in children must be regarded with considerable doubt. Those reported between 20 and 30 are more worthy of credence, and he is convinced that many cases labeled neurasthenia were in reality cases of arteriosclerosis in adults under 30. The unfavorable prognosis generally associated with arteriosclerosis is due to the fact that it is not diagnosed until irreparable lesions are already installed; if we watch for its incipient manifestations earlier in life, there is no doubt that we can cure or at least keep it under control.

89. **Color Test for Albuminoids.**—Lewin calls attention to the delicacy and reliability of the color reaction which follows when dissolved albumin is treated with a mixture of 0.1 to 0.15 parts trioximinomethylen in 100 parts crude sulphuric acid. Even a 0.02 per cent. solution of egg albumin shows the characteristic violet tint.

92. **Photodynamic Action of Mineral Pitch.**—Lewin had his attention called to an itching and *smarting affection* which developed on the exposed portions of the skin in 103 persons engaged in an establishment making electric appliances. Those affected had to handle coal tar pitch, and the itching occurrred only while the parts were exposed to the light. Only 15 of the total 103 complained of itching in the dark. The substance was known to have fluorescent properties; the photodynamic properties of fluorescent substances have recently been emphasized by several scientists. This is the first instance known, however, of a photodynamic action from coal tar. A mild ointment or washing with diluted sapo medicatus soon reduced the itching; washing otherwise had a tendency to exaggerate the itching.

93. **The Biologic Tests of Pregnancy, Etc.**—Laboratory workers everywhere are now hard at work on Abderhalden's "protective-ferment" tests for pregnancy, cancer, etc. Heilner and Petri conclude from the results of their research that positive findings are merely the result of the getting into the blood of some of the individual's own albumin which has retained its chemical individuality. It is immaterial how this albumin gets into the blood; it may be from a hematoma from any source, a crushing injury, inanition, fever, infectious disease, cancer, cachexia—any of these is liable to entail the passage of some unmodified albumin into the blood and the consequent positive reaction. There is nothing specific about it, they state, beyond this.

Lampé and Papazolu applied the test to twenty-five patients with exophthalmic goiter and three with simple goiter, and to a few patients with nephritis or diabetes. The findings indicate that the thyroid secretion, the thymus secretion and also the ovarian secretion are perverted in exophthalmic goiter.

Steising announces that he has succeeded in separating the active ferment into an amboceptor and a complement part; this permits the use of old serums for the test, and renders the technic much more generally applicable. He inactivates the serum by heating to 58 C. for an hour and then reactivates it as desired by addition of fresh male serum. (See Editorial in The Journal, Aug. 16, p. 493.)

99. **Radium Treatment of Cancer.**—Exner has found it possible to enlarge the passage with cancer of the esophagus by treatment with radium, and has thus treated twenty patients. In two cases the cancer perforated into the trachea or mediastinum, and it is possible that this might not have occurred, at least quite so soon, without the radiotherapy. His experience with radium as also with roentgenotherapy has apparently demonstrated that weak dosage, inadequate exposures, have a stimulating influence on the growth of the cancer. In a few instances severe hemorrhage has followed the exposures. He has applied the radium treatment in forty cases of cancer elsewhere and reported in 1910 a permanent cure since 1904 and 1905 in two cases of almost inoperable carcinoma of the buccal mucosa and jaws or upper lip. These are the only ones of the forty patients with deeply rooted cancer who have remained free from recurrence for more than three years after the exposures and both of these have died recently of recurrence, fatal in a few weeks in the first case, after nine years of health. The other patient had a recurrence after seven years but this was apparently subsiding under renewed radium treatment when the woman died of acute phthisis. Of the rest of his material he was able to keep twenty patients in comparatively good health for three or four years and a few for five or seven, when they were evidently otherwise doomed to die of their malignant disease in a few months. Exposure to adequate doses of the therapeutic rays causes an intense proliferation of connective tissue around the growth, thus walling it in, as it were, and preventing the spread to the lymph-nodes in the vicinity. In cases of cancer of the tongue and pharynx in which, under other conditions, the connected lymph-nodes become rapidly involved, they were not invaded. This absence of metastasis apparently confirms the assumption that the efferent lymphatics become impermeable under the influence of the radiotherapy.

127 *Experiences with Eclampsia; 158 Cases. W. Rohrbach.

111. **Operative Treatment of Peritoneal and Genital Tuberculosis.**—Schmidt tabulates the details of thirty-eight operative cases. Two of the patients were moribund and ten others have died since, but twenty-three were restored to health by the operation. Four of the patients were between 15 and 20; twenty-one between 20 and 30, and the oldest patient was over 70. Nineteen are living of the twenty-four patients not given drainage, and four of the thirteen with drainage. One patient with a tuberculous process in the uterine mucosa recovered after curetting alone; another after abdominal hysterectomy; another with a secondary peritonitis but no ascites recovered after curetting and a laparotomy, as also another with effusion, given a supplementary posterior colpotomy. A patient with a tuberculous process in both uterus and tube recovered after panhysterectomy. The laparotomy also cured another patient with a tuberculous tube and peritonitis with effusion. Two patients with tuberculous peritonitis without effusion and tuberculous processes in both adnexa were cured by an operation on the adnexa alone; two others with the same plus effusion, treated by an operation on the adnexa, died, as also two of five after a laparotomy (one moribund).

112 and 119. **Eclampsia.**—Schmidt thinks it is more than a mere coincidence that 6 women succumbed to eclampsia in his service in 1912, while only 3 of 17 died during 1911, although all were treated on the same principles. In his total 98 cases, 1907-1912, 23.47 per cent. of the patients died, including 19 of the 71 intrapartum cases; 2 in the 2 pregnancy cases, and 2 in the 15 post-partum cases. The mortality was 13.3 per cent. in the 15 cases with spontaneous delivery; 24 per cent. in the 45 operative cases; 13.04 per cent. in the 23 cases in which Stroganoff's method was applied and delivery was spontaneous, and 46.66 per cent. in the 15 Stroganoff cases with artificial delivery. It is possible, he remarks in conclusion, that venesection at once, on commencing the Stroganoff expectant, prophylactic treatment might improve the outcome.

Strempel protests against the general assumption that the Stroganoff method cannot be applied in the home but must be reserved for institutions, and relates his experience with four cases in which he applied this method in a wage-earner's home with complete success. He leaves the medicine with written directions for the doses, by the clock, impressing on the family the necessity for keeping the room dark and protecting the patient against noises and other external influences. A rectal syringe holding 10 gm. is left for giving the solution of chloral, one to four syringefuls as ordered. When the patient becomes able to swallow, the medicine is given in the same number of tablespoonfuls by the mouth. The morphin is also given in powder or solution in the same way except when he is at hand to administer it by subcutaneous injection. He keeps in constant telephone communication with the family, and when any change is reported, speeds at once to the patient. The success in the cases reported, with the aid only of the husband or midwife, was certainly brilliant, he declares, and justifies the adoption of the method by the general practitioner, possibly preceded or accompanied by venesection. (The details of the method were given in THE JOURNAL, July 3, 1909, p. 86.)

121. **Importance of Gonorrhea in Management of the Puerperium.**—Hannes warns that an old or latent gonococcus infection is liable to flare up and spread after delivery, and that this is a most cogent argument against allowing women to leave the bed soon after a childbirth. It is extremely important, further, on this account to distinguish which women already have gonococci before delivery; he makes a practice of having the women examined for gonococci just before delivery, and found them in 4 per cent. of 1,753 pregnant women in the last year and a half. These women are then supervised with special care. Even this does not reveal all those affected. In some other women supposedly free from gonococci and allowed to get up at the usual time, the temperature suddenly ran up and gonococci were then found in the lochia. On suspicion of gonococci, internal examinations should be scrupulously avoided, and the women should be kept absolutely quiet in bed for at least two weeks.

127. **Eclampsia.**—In this communication from Küstner's service, 158 cases of eclampsia are analyzed and the conclusion emphasized that the prognosis seems to be more favorable the sooner the delivery is completed. Early and rapid delivery is hence the basis for treatment. Rohrbach warns on principle against venesection before delivery, as one never knows how much blood is going to be lost intra partum. But

after delivery he regards it as a most important aid; he thus applied it thirty-seven times in thirty cases of eclampsia in the last six years, withdrawing 400 or 500 c.c. of blood at a time. Treatment after delivery is based on daily tests of kidney functioning and the pulse. Of the sixty-five patients with eclampsia before or during delivery, in the last six years, 16.92 per cent. died and 13.63 per cent. of the twenty-two women with post partum eclampsia.

128 *Spreader to Hold Open Suppurating Process. (Verwendung von Spreizfedern bei der *Behandlung eitriger Prozesse.*) M. Tiegel.
129 Technic for Operative Treatment of Hydrocele. Müller.

128. Spring Spreader to Hold Open Suppurating Processes.—Tiegel has found very useful a little retractor with spring which holds the lips of a phlegmon apart after its incision and permits the escape of the thick secretions without the injury of tissues almost inevitable with other methods of treatment. Application of the spreader for even twelve hours transforms a phlegmon on the hand into a rapidly healing process, much shortening its duration and leaving the functioning unimpaired. He devised the little instrument for suppurating processes on the fingers in particular, but found it so useful that he now applies it regularly in mastitis, abscesses in the neck or around the kidney, etc. An illustration of it is given.

132 *Prophylaxis of Hereditary Syphilis in Foundling Asylums. (La profilassi dell' eredo-sifilide nei brefotrofi.) A. Gallico.

132. Prophylaxis of Inherited Syphilis in Foundlings' Asylums, Etc.—This entire number of the *Policlinico* is devoted to syphilis, with summaries of the more important recent articles on the subject in international literature. Gallico's is the only original article, and he states that the experiences with the Wassermann test have been most disappointing in infants' asylums. It was hailed especially in these institutions as promising to solve the ever-pressing question as to whether a foundling has a syphilitic taint or not, and thus whether it can be given to a healthy wet nurse or whether it is safe to give it to a syphilitic wet nurse. The test has proved a great disappointment. During the ten years 1901-1910, 3,432 infants were received and only 202 had unmistakable signs of syphilis. Of this group only thirty-nine developed symptoms during the first ten days; eighty-three between the tenth and twentieth day; three between the eightieth and ninetieth days; one not until after four months and one after five months. The Wassermann test was applied in sixty-four cases in which the ultimate history of the child was learned. In six cases the reaction was positive and the children developed symptoms later; in twenty-seven cases the response was negative and the children have never shown any signs of syphilis. In thirty-one cases, however, the response was negative and yet the course of the cases or the necropsy findings revealed unmistakable syphilis. Similar contradictory findings have been reported in Italy by Dalla Favera, Flamini, Serra, Gentile, Fua and Pennato. Some report a positive reaction when nothing at the time or during the years since has indicated the presence of syphilis.

Examination for the spirochetes is also misleading as they are discoverable only in accessible lesions. Forty-six of the children who were rather above the average size and weight developed symptoms of syphilis later. At present, he says, the only guarantee of approximate safety is to wait for fifteen up to forty days before deciding whether the infant is syphilitic or not; by the end of this period the question is generally decided one way or the other. Science to date has nothing better to offer.

136 *Pathogenesis and Treatment of Epilepsy. G. C. Bolten. Commenced in No. 25.

133. Practical Importance of the Syphilis Index.—Sormani's modification of the Wassermann reaction gives a definite index for the syphilis, and not only a qualitative but also a quantitative analysis; thereby serving as a guide in the treatment of the disease. This syphilis index has much in its favor in comparison to the opsonic index. It is delicate; gives always the same results; has a prognostic value, and in many instances indicates the stage of the disease. Sormani claims that the test deserves the name he has given it on account of its importance and practical value.

136. Epilepsy Due to Insufficient Thyroid Functioning.—In this lengthy article Bolten sets forth that "genuine" or essential epilepsy is a toxicosis caused by normal food-products, as well as by chemical cell products, when these products fail to be sufficiently neutralized by the action of the thyroid and parathyroid glands which normally serve to protect the central nervous system against toxins. The insufficiency of the glands in this protecting function may be secondary, due to some derangement of some part of the sympathetic nervous system. The changes found in the brain cortex are secondary, and are the result of the chronic intoxication. He declares that essential epilepsy is curable by thyroid treatment. By injections of fresh juice expressed from the thyroid and parathyroid glands of beef cattle, it is possible to cause a complete disappearance of the symptoms of essential epilepsy. He adds, however, that in many cases it is impossible to distinguish between essential and symptomatic epilepsy.

138 *Avoidable Cause of "Salt Fever" in Infants. (Undersøgelser over Kogsaltfeber hos spæde Born.) G. Jörgensen.

138. Salt Fever in Infants.—Jörgensen reports experiences and experimental research which have apparently established that the rise in temperature in infants after injection of salt solution is due to the same cause as the somewhat similar disturbances observed after injection of salvarsan in some cases, namely, to contamination of the water vehicle by the presence of toxic substances from the bodies of bacteria in the water. The bacteria are killed by the preliminary sterilization but the bodies are left, and this is sufficient to explain the "salt fever" in infants and the *Wasserfehler* after injection of salvarsan. His findings call for a revision of all the work on "alimentary fever" in infants, as he found that the rise in temperature followed constantly when the salt solution was made with distilled water which had stood for some time, while it was never observed when the water was freshly distilled. Consequently the statements as to the danger of subcutaneous infusion of salt solution in infants are shown to be unfounded if the water is free from bacterial contamination.

The Journal of the American Medical Association

Vol. LXI, No. 9 CHICAGO, ILLINOIS AUGUST 30, 1913

A FINAL WORD TO THE FELLOWS AND MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION [*]

A. JACOBI, M.D.

NEW YORK

The duties and responsibilities of your presidents are such as to prevent them from addressing you frequently in your open meetings. That is why I avail myself of the courtesy of the Editor of THE JOURNAL, which permits me to deliver a brief valedictory to my friends all over the country and to add some remarks in connection with the subject discussed in the inaugural address[1] I delivered on June 4, 1912.

Advancing years have added to the greatness of the edifice called the American Medical Association. It has served you, its constituents; it has benefited the American people. From year to year its scientific work has expanded and its civic importance increased. Its Judicial Council and its councils on Health and Public Instruction, Medical Education and on Pharmacy and Chemistry, have submerged scores of inferior medical schools, enlarged knowledge, opened new horizons and fastened the links between all classes of citizens.

Not to lag behind my own obligations as a citizen of the land and a physician of the people, I tried a year ago to trace for you a part of the neglected congenital and earliest causes of the 17 per cent. of the early infant mortality, which trace their origin to embryonal and fetal life, and to the dangers of parturition and vicissitudes of the first days and weeks of the new-born. The vast number of infant deaths and the still greater amount of woman's invalidism and decrepitude were merely referred in part to social shortcomings, to the prevalence of the sickly incompetency which is called charity, to the lack of state or municipal responsibility, and to the inefficiency of medical and other service. Such service when inadequately rendered by doctors and midwives and nurses has been frequently and vociferously censured for its inefficiency.

Having shared in that kind of work part of these sixty years I bow my head with the rest of us, but I do not graciously submit to the reproaches heaped on the obstetric professors who always promise the achievements they expect in future of their medical students. On the other hand, I cannot agree with the complaint that when professors are teaching midwives, "medical students are deprived of their teachers' time"; nor do I fear with a modern author lest the midwife compete with the physician. That has been said in earnest, still it is only ludicrous. I want here to repeat merely the objects of English midwifery schools, which are "the care of the expectant woman, the conduct of normal labor, the care of babies immediately after birth, and the simple principles in an urgent case of artificial feeding."

At my time of life my opportunities to do good may not be many. That is why I refer in a few sentences to my discussion a year ago on what I considered the best means of combating infant mortality. The attention this topic has aroused has been close and various. Now a vast number of papers and pamphlets and books have been written to illustrate the subject of artificial feeding of the infant. It is no longer indicated, however, to rehash the fact that no less than 20 per cent. of the babies when fed on conscientiously selected artificial food will die before the first year of their lives terminate, while only 7 per cent. will be carried off when fed on human milk. In the brief space at my disposal to-day I shall not return to that topic.

I also directed your attention to the many causes of death acting before and immediately after birth, many of them not counted in mortality statistics. Indeed, officially, stillbirths are in most of our states not considered at all. One of those causes is the absence of proper attendance on the mother during pregnancy, and during and immediately after labor. I discussed the shiftless lack of attention paid to the expectant woman and to the necessity of teaching and licensing and supervising midwives.

I emphasize the subject again, thinking, as I then thought, that the communities and the commonwealths have no more important and beneficent service to render to themselves and to the nation, and that the President of your Association and the members of our profession have no more dignified duty than to contribute to the salvation and the well-being of the people. I have nothing now to add to my statements contained in THE JOURNAL[1] last year and the *Medical Record* and the *New York State Journal of Medicine* of the same date, and nothing to report which would amount to a criticism of a number of papers written since that time —a few directed against the position taken by me. Some are contained in the "Transactions" of the third annual meeting, held at Cleveland, Oct. 2-5, 1912, of the American Association for the Study and Prevention of Infant Mortality. I beg to insist on your spending an hour, every one of you, on the fifty pages dedicated to the chapter on midwives. If there you read in the paper contributed by an obstetric professor, as also in a similar production of his which appeared this year in THE JOURNAL,[2] about your President's "utter foolishness" in making certain recommendations, you must not, I hope, drift away from your knowledge of the advisability of hearing both sides.

---

[2] Ziegler, C. E.: The Elimination of the Midwife, THE JOURNAL A. M. A., Jan. 4, 1913, p. 32.

This I know: that last year I rose before you because I knew that neither you nor I had a more important interest or a more urgent duty than to look out for the necessities of the people, of which after all the professors are only a small and sometimes an insignificant part. In the opinion of my critic I have taken "a decidedly backward step" as regards both the teaching and practice of obstetrics; but in my remarks I never thought of obstetric teaching in the medical schools. A "backward step" would amount to a step into something like a nonentity. For he cannot help quoting an authority according to which only a single school in America has adequate facilities for properly teaching obstetrics to American students.

According to Abraham Flexner, thirty-one medical schools of the same high standard as one he mentions are needed in this country. To supply them thirty million dollars and from fifteen to twenty years at an annual outlay of three million dollars are required—so we are informed—for affording an adequate instruction in obstetrics to our medical students. These students must have the privilege of commanding, so it is asserted, all the material to practice on and to learn by. What is meant by "material"? Nothing else but the present and future mothers of your fellow-citizens. That is why the outlook in Pittsburgh with its recent combination of hospitals and dispensaries is said to be very promising. Promising of what? I said a year ago and say again that I do not care to wait fifteen or twenty years for the promise held out to future students or doctors whose primeval forest of ignorance is generally deplored by those who ought to know from their professional experience, and I repeat that I respect and urge the right to live, as much of the hundreds of thousands of women and newly born of to-day, to-morrow and a year from now, in the towns and in the rural inaccessible solitudes, as those who are to follow in twenty years.

In my inauguration address of last year I did not care to refer to the future instruction in obstetrics for the students of medicine in Pittsburgh and elsewhere, and for future practitioners. I dealt with the salvation by sufficiently instructed midwives now and forever, of women and their infants. My subject was confined to hundreds of thousands of them in the ghettos, the congested city quarters and the rural districts into which you and perhaps I do not easily descend; in which no doctor of skill and knowledge is tempted to locate. In Pennsylvania alone there are 100,000 births annually in rural places with no hospital near; with no opportunities for clinical services of large cities, and very few ill-prepared and overworked doctors.

The student question is another problem. For that opinion of mine a professorial oracle calls me a fool—an "utter fool," when it is he who unskilfully changes the topic under consideration and who clinched his arguments by merely quoting himself a second time literally and repeating his convictions of my "utter foolishness." If this is presented as an argument, it is a serious matter and not to be touched with a silk glove. My horizon and years extend beyond the pelvis of the poor woman of the large cities blessed with a medical school and an eager professor. It comprehends the necessities of what is called the student material, meaning the upper and lower classes of the people at large. But after all, I do not recognize the division of our people into superior and inferior classes. The superior rich are too often useless Americans. They have not even children. The so-called inferior create the wealth of America in children, in labor and in brains, and the back-bone of the land. These derided inferior classes, your "material," gave us the Lincolns, the Clevelands, the George W. Curtises and the Carl Schurzes.

What has the nation done for them? From an unprinted late report of the Committee on Blindness of the New York Association for the Blind, which I am permitted to use, I take the following facts:

Midwives are allowed by law to practice unrestricted in twelve states, Alabama, Arizona, Arkansas, Florida, Georgia, Idaho, Kentucky, Maine, South Carolina, Tennessee, Virginia and West Virginia.

There are no laws relating to the training, registration or practice of midwives in fifteen states, namely, California, Delaware, Massachusetts, Michigan, Mississippi, Nebraska, New Hampshire, New York, North Dakota, Oklahoma, Oregon, Rhode Island, South Dakota and Vermont. In the twenty-two states in which there are laws relating to midwives, fifteen require that they shall be licensed and that they shall pass an examination before being licensed to practice, while nine restrict the practice of midwives to attendance on normal cases. In no state is there provision by state law for supervision of midwives in their practice. In six states it is required that midwives shall be trained, but in no state are there any standardized schools. Only Bellevue Hospital, the Philadelphia City Hospital, where women are received for midwifery training on the recommendation of the board of medical examiners, St. Louis, and lately Newark, N. J., have schools. Meanwhile, so far as officially known, 34 per cent. of all cases of births in the whole country are reported by midwives. Unfortunately, however, the statistics are wofully incomplete.

Of other information I submit the following:

In 108 cases of ophthalmia neonatorum that are reported by various eye clinics, sixty-two patients were attended by physicians, forty-three by midwives, and three by neighbors. Of the sixty-two, prophylactics were used in fourteen; of the forty-three, in eleven. Out of eleven, six lost one eye, three were merely scarred, and three were blind. It so happened that all the cases of total blindness occurred in the practice of physicians.

Literature is getting too large. So many papers are published that nobody has time to read them. Everybody has just time to miss or forget, or to bury in waste-paper baskets, which profit of most of them.

Now, are our fault-finders correct? Are more babies saved, more women kept in health by a promise of erudite and well-prepared doctors of the future? Is sepsis of the lymph-vessels, the pyemia of the blood-vessels to-day prevented by promises? Even the German Empire has 15,000 cases and 5,000 deaths annually of puerperal fever. Prussia alone, 5,044 and 1,772, for the doctors in these countries are officially admitted to be immature, and the number of midwives, trained in a year, insufficient in numbers. They know how to keep accounts in Germany. There the deaths from puerperal fever are 35.1 per cent., compared with scarlet fever 7.8 per cent., diphtheria 11 per cent., and typhoid 14.1 per cent., and ours, no matter whether they are called puerperal fever or peritonitis, or nephritis, or pneumonia, are surely no less. After all, acknowledging the drawbacks of our social conditions, what I demanded was nothing but less work, less filth, less starvation, less physical and factory work of the pregnant woman and new mother, and altogether better social conditions. Indeed, more hospitals are required by those who cannot help preferring absence from their homes. After all, however, it is only the primipara that should be offered and accept a bed in the hospital. The woman with children belongs to her home, where her mere presence is wanted as a protection to her flock.

It is true, the Lying-In Hospital of the City of New York, which is the admirable creation of J. P. Morgan, has succeeded in aiding during 1912, outdoor and indoor, in 5,600 cases of confinement, but in the same year eight times as many confinements were attended by midwives, good, bad and indifferent.

Modern institutions like this, like modern Morgans, are welcome. I wish, however, there were no social conditions which make them necessary. Still I must wish there were more like them. After all, as you cannot have them, and not even enough professors or doctors to go around, be sure not to "eliminate"—that is the pet modern expression—the midwife, but to see to her municipal, state or national education, training, licensing and supervision.

FETAL PERITONEAL FOLDS

AND THEIR RELATION TO POSTNATAL CHRONIC AND ACUTE OCCLUSIONS OF THE LARGE AND SMALL INTESTINE *

JOSEPH RILUS EASTMAN, M.D.
Clinical Professor of Surgery, Indiana University School of Medicine
INDIANAPOLIS

In the region of the caput coli and ileocecal junction, there appear frequently after the fifth fetal month certain peritoneal folds of fairly constant form and distribution which stand forth without manipulation and spread out so prominently that they can scarcely be overlooked. They are either anatomic or pathologic entities, and surely are not brought into existence by any artifice of traction or manipulation.

Frequently sheets or broad bands of serous membrane pass from the mural peritoneum over the front of the cecum and ascending colon, sometimes greatly lessening the caliber of this part of the large intestine. These are the bloodless fold of Treves and the parietocolic fold. The latter, according to Douglas Reid, was first described by Jonnesco. It resembles the pericolic membrane of Jackson as seen in children and adults.

Other fetal folds suggest by their position and attachments a causal relationship to gravitations and angulations of the terminal ileum. For example, the genitomesenteric fold described by Douglas Reid of the University of Cambridge, a fetal fold which passes from the mesentery of the terminal ileum down into the pelvis attaching below to the genital gland, bears an interesting resemblance to the so-called ileopelvic band, an anomalous band occasionally passing from the terminal ileum into the pelvis in the adult, to which Mr. Arbuthnot Lane ascribes an important rôle in the causation of Lane's kink. Figures 1, 2 and 3 show the genitomesenteric fold of Reid. These are photographic enlargements of smaller photographs sent to me by Mr. Reid, and are part of a set similar to that recently accepted by Professor Keith for the Royal College of Surgeons.

Reid's genitomesenteric fold is continuous above with the duodenorenal ligament of Hueschka, and we have here at least a speculative explanation of the kinking upward of the terminal ileum. Another fold not above suspicion in cases of upward displacement of the terminal ileum is the rather constant ileocolic fold which, if contracting, would draw the terminal ileum upward and toward the ascendong colon (Fig. 4). Likewise the so-called root folds, as the left or superior root fold shown in Figure 5, or the right root fold, the mesentericocecal fold of Jonnesco, which are ridge-like upward reflections of the mesentery, indicate the marked tendency to irregularities of attachment and upfoldings of the mesentery.

I have had little difficulty in finding Reid's genitomesenteric fold in fourteen out of thirty-two fetuses examined (Fig. 6). I have also been able to demonstrate it in the adult where it had caused a kink and where it had produced no kink of the ileum. By picking up the terminal ileum in an adult, a tall, sickle-shaped fold of peritoneum passing from the mesentery of the terminal ileum to the internal abdominal ring came up much too freely to admit of suspicion of its having been produced by traction. Reid likewise has demonstrated the genitomesenteric fold in the adult. Illustrations in one of C. H. Mayo's published articles show a band corresponding precisely to Reid's fold which he divided for the correction of a Lane's kink.

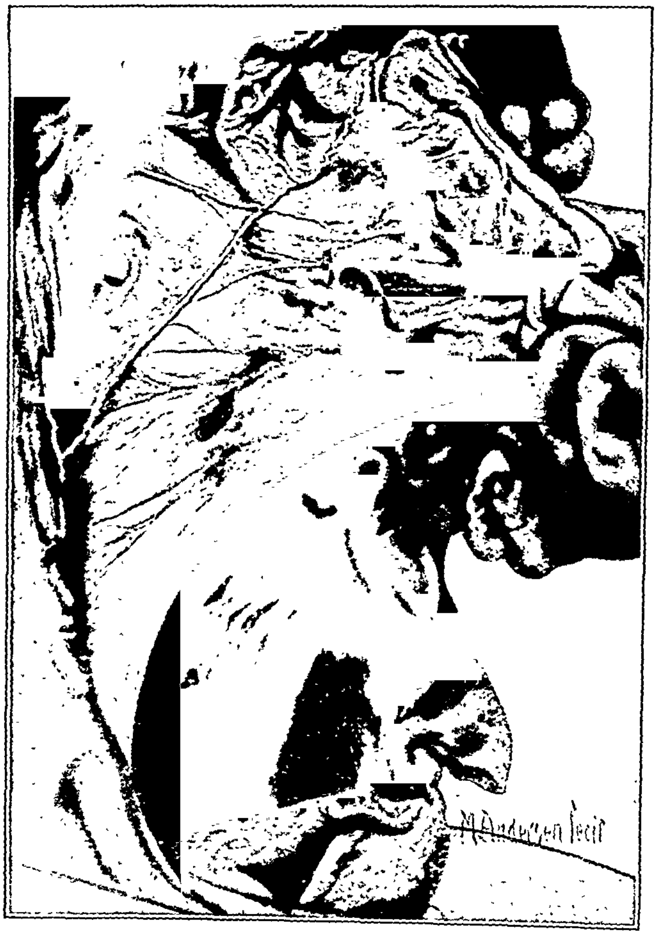

Fig. 1.—The genitomesenteric fold of Reid. The white sickle-shaped band is seen passing from the terminal ileum down into the pelvis.

Mr. Lane[2] describes his ileopelvic band as a new or acquired distinct peritoneal ligament which attaches itself progressively to an area of the ileum more and more distant from the attachment of the normal mesentery. If Lane's ileopelvic band is not a persisting fold

---

* Read in the Section on Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

* Because of lack of space, this article is abbreviated in The Journal. The complete article appears in the Transactions of the Section and in the author's reprints. A copy of the latter will be sent by the author on receipt of a stamped addressed envelope.

[2] Lane, W. Arbuthnot: Brit. Med. Jour., May 4, 1912.

of Reid, it is an interesting coincidence that the fetal structure should be precisely similar in its position and attachments to the adult band; and if, as Mr. Lane says, and as I have no sufficient reason to question, this fold is due to a crystallization of forces to resist the descent or displacement of intestines, then this crystallization surely takes place in fetal development.

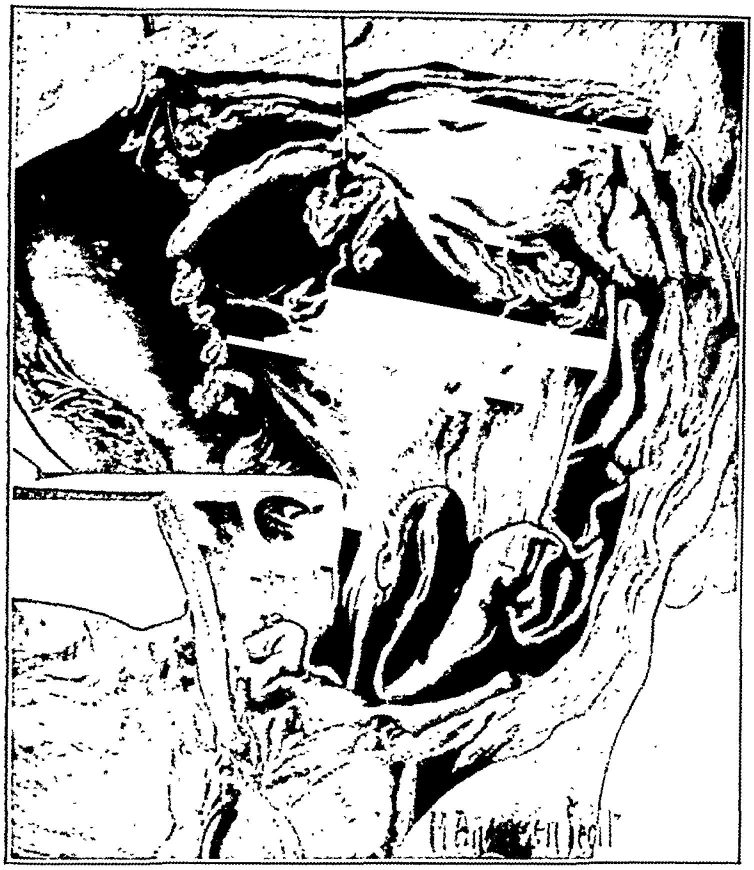

Fig. 2.—A genitomesenteric fold of Reid passing upward from the genital gland to the mesentery of the terminal ileum.

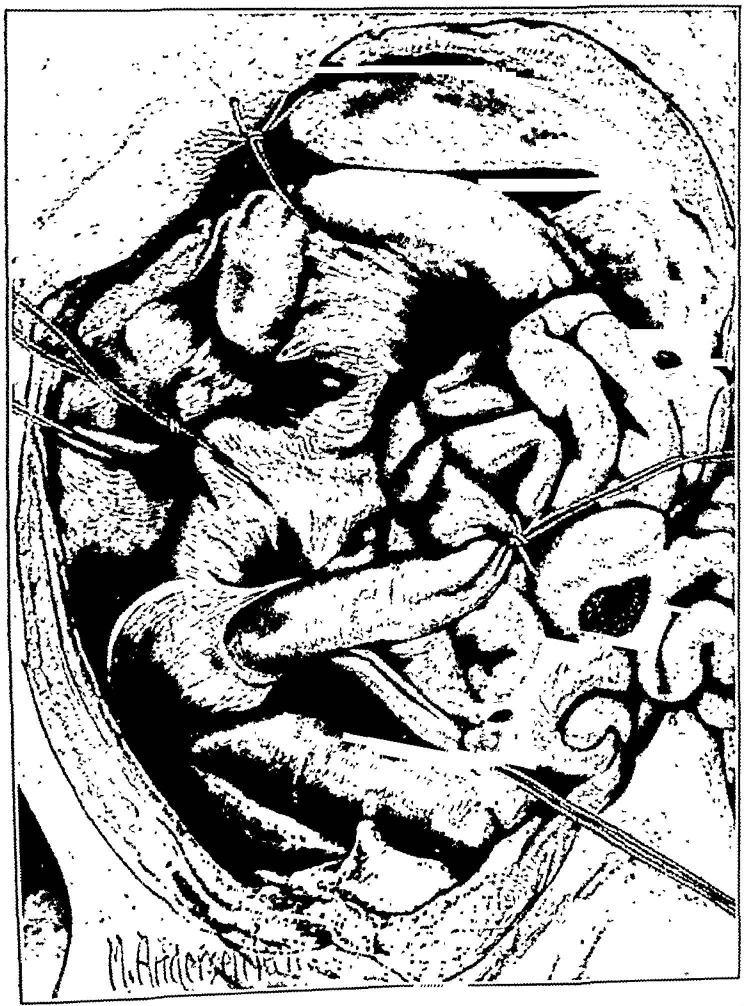

Fig. 4.—The ileocolic fold extending from the upper lamina of the mesentery of the terminal ileum around over the cecum.

In the case of the genitomesenteric fold, a simple if somewhat suppositional explanation of origin is that in the descent of the right ovary or testis the dorsal peritoneum is caught and dragged or drawn out into this form.

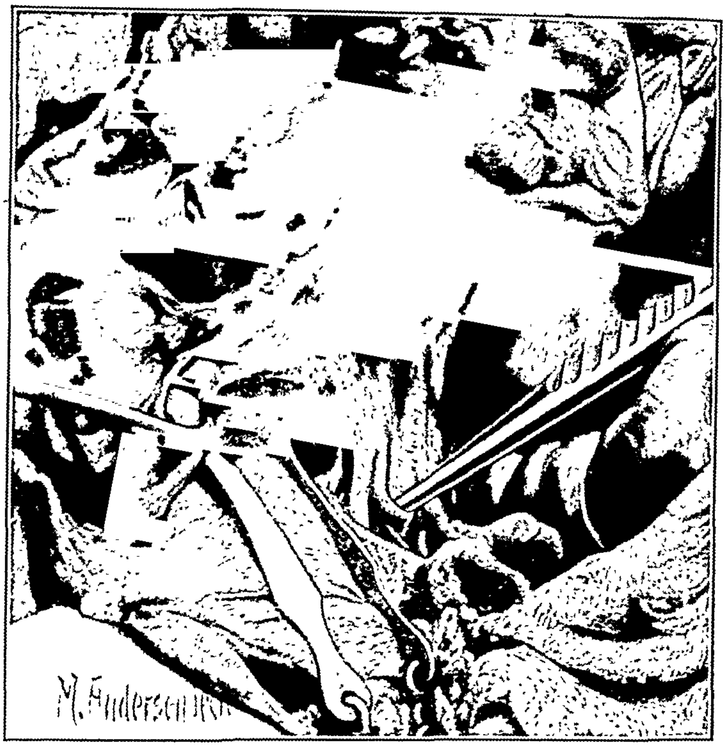

Fig. 3.—The genitomesenteric fold of Reid. A heavy band passing from the terminal ileum into the pelvis.

There is considerable evidence to support the assumption that the bloodless fold of Treves begins as an adhe-

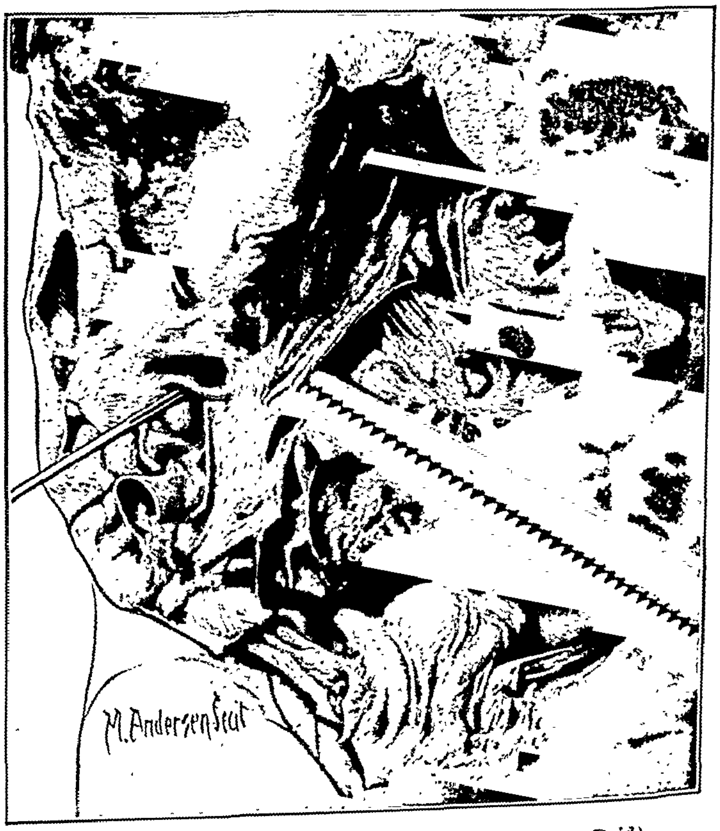

Fig. 5.—The superior root fold (after Douglas Reid).

sion between the cecal head and the mural peritoneum, as shown in Figure 7, and that later in the act of cecal torsion the caput coli rolls itself, so to speak, in serosa drawn over from the very loosely applied peritoneum of the lateral abdominal wall, as a man rolls himself up in a blanket; for the bloodless fold of Treves may be found as a short band of adhesion, as shown in Figure 7, as a somewhat longer band as shown in Figure 8 (dissection of an adult by Reid), or as a sheet long enough to extend from the lateral abdominal wall, beginning at a point opposite or below the level of the cecal head, and extending upward and inward, to be attached to the mesentery of the terminal ileum, and forming a shirt-pocket-like fossa in which the caput coli and vermiform appendix may lie ensconced (Figs. 9 and 10). It seems fair to suspect that the parietocolic fold is formed by similar fusion at a higher level.

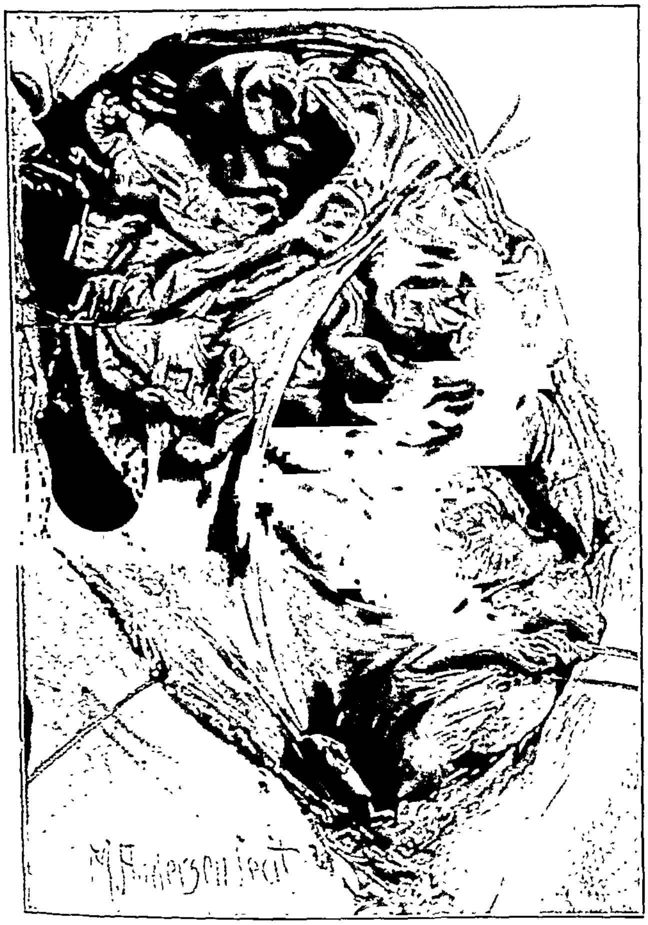

Fig. 6.—The genitomesenteric fold of Reid is the sharp sickle-shaped band at the right of the picture. Laterally to this band is the bloodless fold of Treves passing from the mural peritoneum to the caput coli.

It may fuse with the peritoneum covering the caput coli.

I believe that the bloodless fold of Treves not rarely persists in the adult, and forms the boundary of a precolic fossa in which the cecal head and appendix may be tightly embraced (Fig. 9); and further, that during operations for appendicitis, it is likely that the caput coli with the appendix is not rarely shelled out of this anomalous peritoneal pocket; the peritoneal membrane, that is to say the bloodless fold of Treves, which forms the pocket, being looked on by the operator as an affair of adhesion formation.

Another rather common fetal fold which, persisting and contracting, may bind down the appendix or envelop it, is illustrated in Figure 11. Here a skirt-like fold

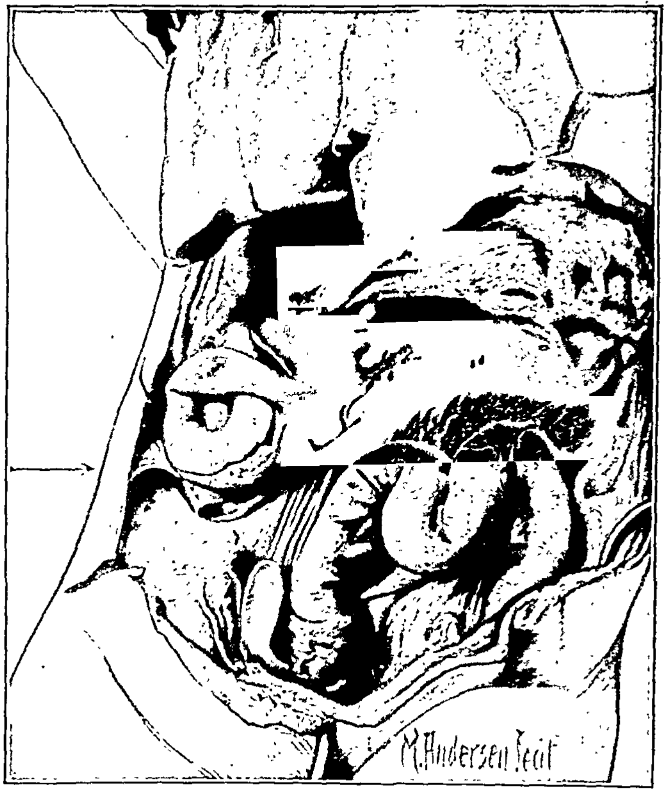

Fig. 7.—A beginning bloodless fold of Treves being formed by the stretching out of an adhesion forming between the caput coli and mural peritoneum before normal cecal torsion (after Douglas Reid).

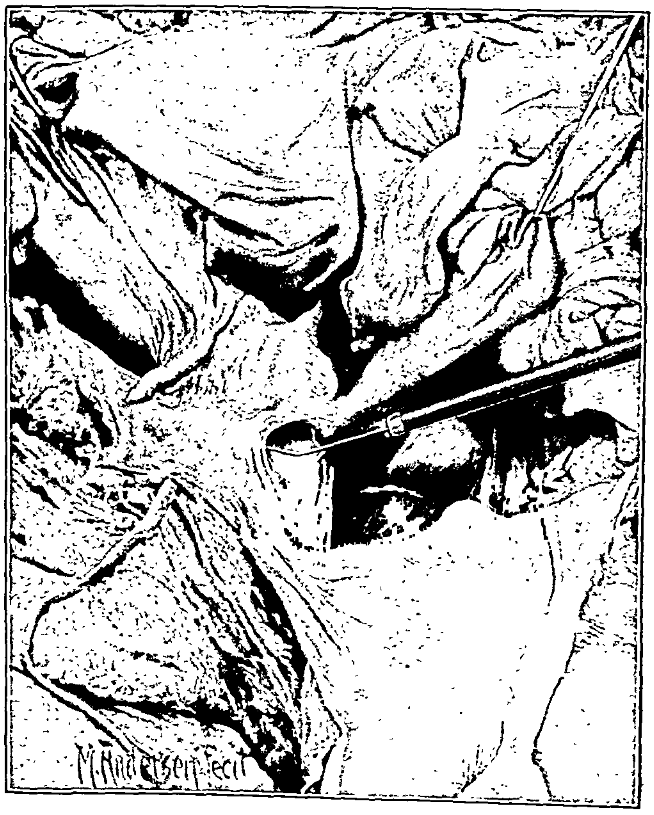

Fig. 8.—A bloodless fold of Treves somewhat more fully developed than the narrow adhesion-like fold in Figure 7. (Enlargement of photograph by Reid.)

passes from the terminal ileum above, downward around the appendix, embracing the basal half of the appendix, and then passing upward is inblended with the serosa of the caput coli. The appendix rests in this fold like a man seated in a hammock, or like an injured forearm placed in a sling. (Fig. 11.)

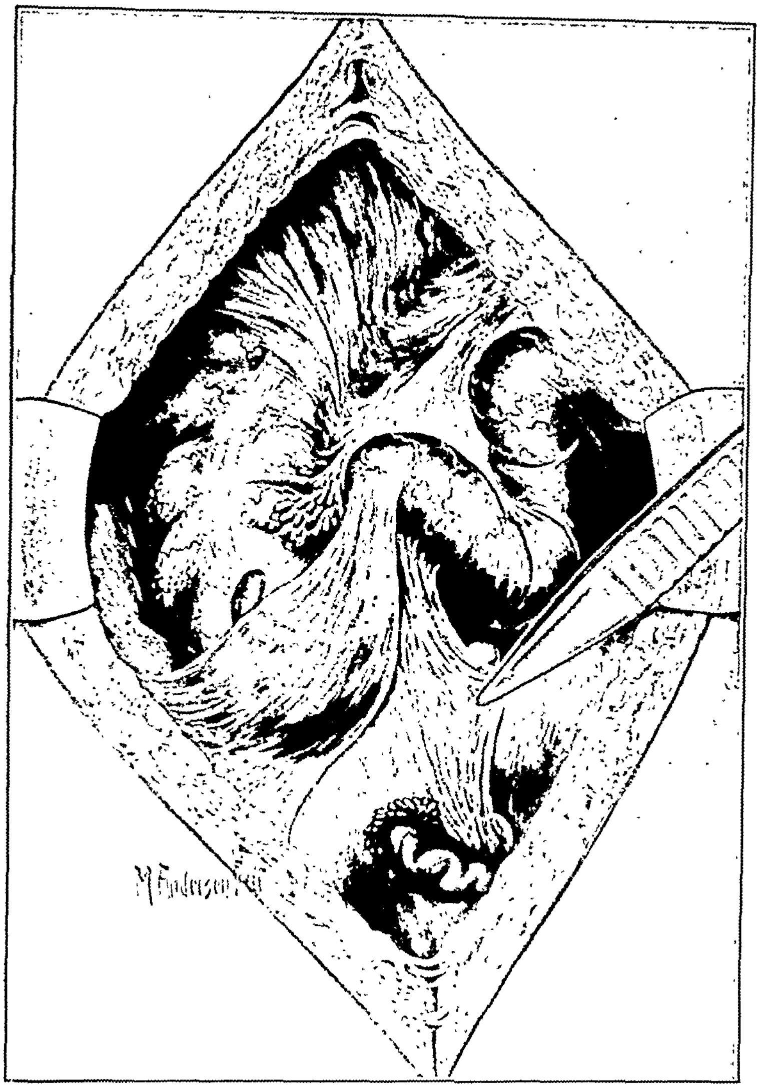

Fig. 9.—Above, the parietocolic fold of Jonnesco passing from the mural serosa across the ascending colon to the inner lamina of the meso-colon. Below to the left the bloodless fold of Treves forming a sconce from which in adults the caput coli must occasionally be shelled out. To the right below the genitomesenteric fold of Reid.

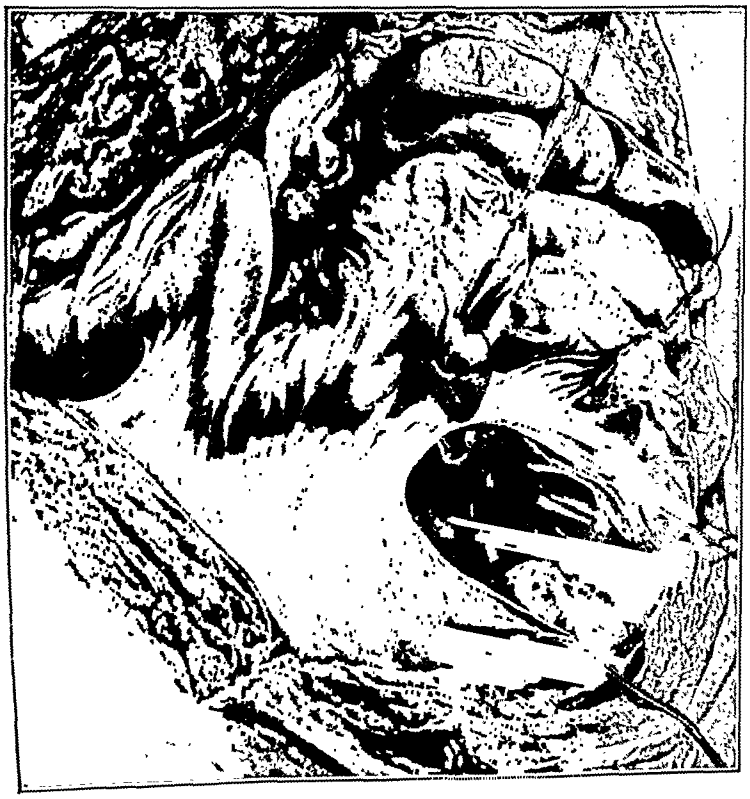

Fig. 10.—The bloodless fold of Treves passing from the mural serosa to the cecum.

Douglas Reid and Byron Robinson have called attention to adhesions of the colon to the peritoneum of its own mesentery. That is to say, along the line where the lateral mural peritoneum passes over to become the peritoneum of the outer lamina of the mesentery of the ascending colon, it first passes up for a short distance, as an upward reflected fold adherent along its upper border to the ascending colon laterally, then passing down and again upward and around over the ascending colon to form its normal peritoneal covering. I have

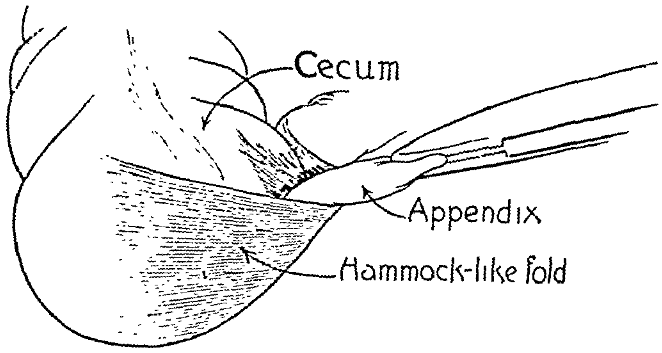

Fig. 11.—A fold passing from the terminal ileum around and below the vermiform appendix and passing upward over the caput coli. The appendix lies in this fold like an injured forearm in a sling.

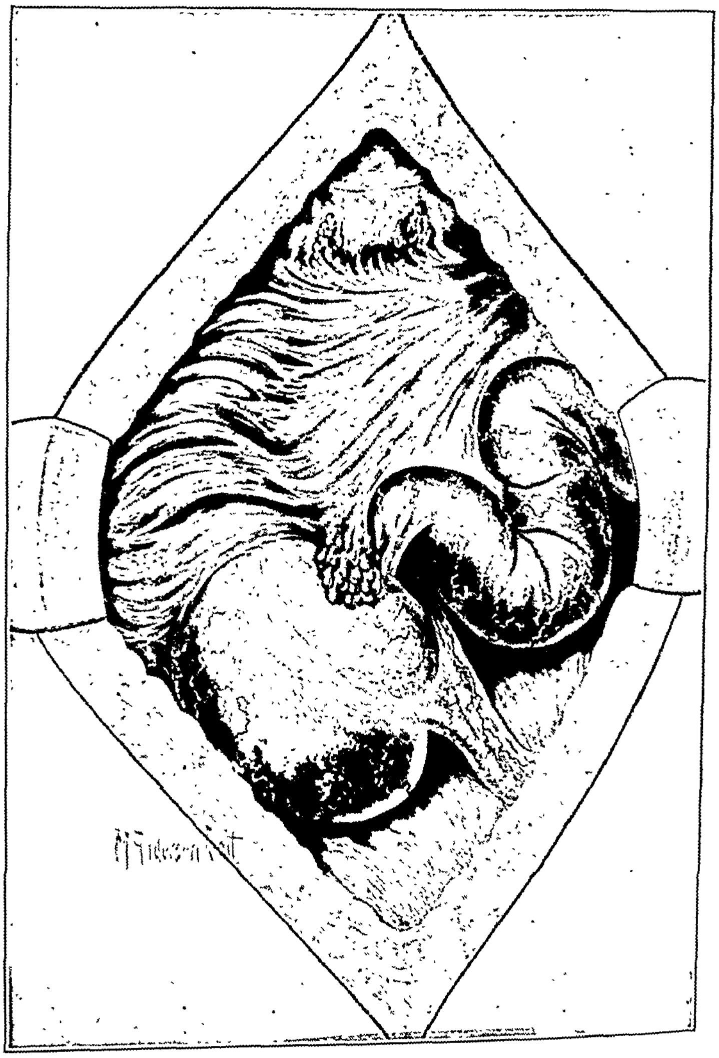

Fig. 12.—A parietocolic fold or Jackson's membrane which produced an acute complete obstruction of the ascending colon with ileus. Blood-vessels passed freely from this anomalous sheet over on the mural peritoneum.

seen in operations on the adult the peritoneum of the mesentery of the ascending colon reflected upward and adherent to the colonic peritoneum for a distance of 5 or 6 inches.

As it was also seen by Douglas Reid in the fetus, it does not seem unfair to suspect this upward reflection of the mesenteric peritoneum of being a persisting fetal adhesion. We have here presumptive evidence that Jonnesco's fold or the parietocolic fold is due to adhesion between the cecum and the mural serosa before cecal torsion has taken place, and that with subsequent rolling inward a sheet of peritoneum is drawn from the lateral abdominal wall as it rolls from left to right.

Reid describes two cases in which the parietocolic fold was formed by a large appendix epiploica. The first step in the development of the parietocolic fold and of the bloodless fold of Treves may be made clearer by assuming that before cecal torsion takes place a large appendix epiploica or several appendices epiploicae become adherent to the parietal peritoneum and elongate and spread out as the colon rolls over from right to left.

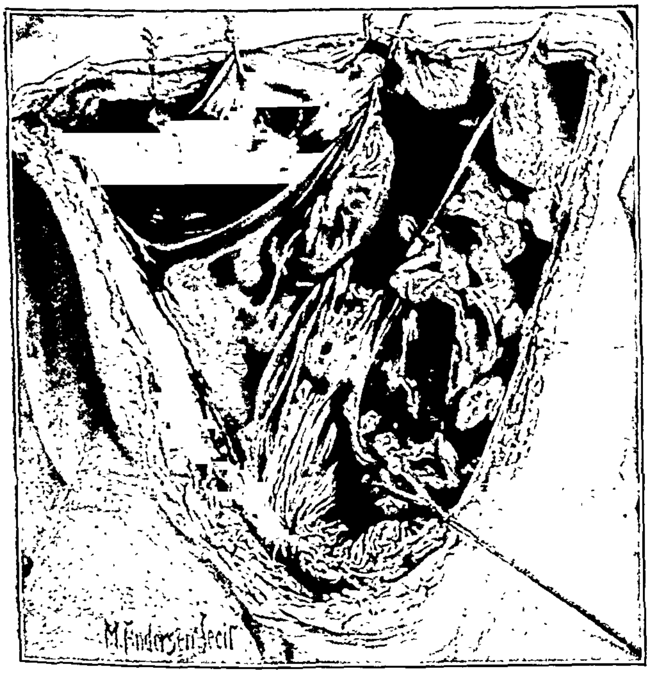

Fig. 13.—A parietocolic fold producing strangulation of an ascending colon in a fetus, a condition strikingly similar to that observed in an adult and illustrated in Figure 12.

So far as I am aware, however, no causes have as yet been reported in which a pericecal membrane completely strangulated the large intestine, producing acute obstruction with ileus. That extensive pericecal membrane formation may lead to acute complete obstruction was shown by the following observation:

REPORT OF CASE

Jan. 18, 1912, R. H., aged 24, was admitted to the surgical service of the Indianapolis City Hospital with a provisional diagnosis of acute obstruction of the bowel. On failure to obtain results from high enemas the abdomen was opened, and I was able to demonstrate a tight compression of the ascending colon, as illustrated in Figure 12. A distinct, smooth, continuous sheet of anomalous peritoneum was not present. The membrane was web-like, and to some extent loculated. There was little doubt, however, that it was an anomalous peritoneal covering which was continuous with and passed from the mural serosa, over the ascending colon, to be inserted in the inner side of the mesentery of the ascending colon, for the blood-vessels passed freely from the membrane onto the mural serosa. There was no sign of infection or inflammation anywhere in the abdomen. The membrane was split up with scissors on the operator's finger as a guide, passed between the anomalous membrane and the normal peritoneum of the ascending colon. The man recovered duly, and up to the present has had no recurrence of his trouble. I have twice seen in the fetus a pericolic membrane tightly compressing the ascending colon (Fig. 13).

331 North Delaware Street.

SURGICAL ASPECTS OF INTESTINAL STASIS, FROM AN ANATOMIC POINT OF VIEW *

JOHN E. SUMMERS, M.D.
OMAHA, NEB.

It seems to me that it would be like carrying coals to Newcastle to attempt to discuss the subject of intestinal stasis in any but a restricted sense. Much has been written about intestinal stasis, from the points of view of both the physician and the surgeon, but nothing of great importance has been added, throwing light on it, from the surgeon's standpoint, which has increased our knowledge beyond that which we received from Lane and Jackson. Lane may be an extremist and his surgery may need some toning down, but his deductions are based on sound premises. Jackson made a great discovery in his "pericolic membrane," and his clinical diagnosis of its presence and the attending pathology has not been improved—it is standard.

During the past year two notable papers have appeared, one by Flint, in the Johns Hopkins Bulletin, and the other by Rilus Eastman (*Journal of Surgery, Gynecology and Obstetrics*), read before the Western Surgical Association, which settle conclusively the mooted point as to the origin of the much-discussed peritoneal bands and membranes of Lane, Jackson, Jonnesco, Reid, Treves and others. They are all congenital and have been recognized and described by anatomists for generations, but that any one of them had a clinical significance other than in the formation of fossae for the possible development of retroperitoneal hernia, appears to have escaped attention until Lane and then Jackson recognized and demonstrated the fact. Lane himself says that after he had called attention to the mechanics of chronic intestinal stasis, the existence of the membranes and bands which he is pleased to designate "acquired mesenteries and adhesions" were "absolutely and categorically denied by physicians experienced in post-mortem work, who appeared to think that, because they had escaped their observation as many things have done and will continue to do, they were justified in denying their existence in the most dogmatic manner possible."

Last summer I had the opportunity of seeing and examining some of Mr. Lane's patients before operation, witnessing his work and examining and talking with some of his patients who were convalescent from operations for the relief of chronic intestinal stasis. So favorably was I impressed with the reality of the subject that during the past year I have sought every opportunity for enlightenment as well as a critical study of my own patients, in order to come to some conclusion for myself as to the frequency of the membranes and bands considered responsible for the symptoms of intestinal stasis from its mildest to its most severe forms. In my experience as I have gained better opportunities for observation through longer incisions, I have come to the conclusion that membranes of the pericolic type of Jackson may be found in every abdomen, if not on the right side in the lower, middle, or upper quadrant, then in the lower left quadrant. We must ever bear in mind that in great measure, the relative relations and displacements of the viscera depend on the conformation of the skeleton, and that there are quite as great variations in the abdominal viscera as there are in the faces of their owners. As before stated, these delicate membranes which we find about the ascending colon, ileum, cecum, involving or not the vermiform appendix, have been described by anatomists for generations. It is the rule rather than the exception that when they do produce symptoms it is in adults, and not in children. Many times the adults are beyond 50 years of age, and up to the time of the commencement of the symptoms, there has never been a sign of anything wrong within the abdomen that could be attributed to the membranes. Therefore these membranes should be regarded as purposive rather than offensive. All of the different types of these membranes may early become offensive, producing angulations of the bowel with their necessary consequences. These instances are congenital defects the same as are cleft palate or supernumerary toes. Continued abuse of function, particularly of the cecum and ascending colon, results in loss of tone, and the membranous supports always present in greater or less extent in every individual, instead of being conservative, become restrictive in the same sense as I have shown elsewhere that the chest wall hinders the action of the damaged, tethered heart in adhesive mediastinopericarditis, and that the overlying ribs should be removed in order that the heart may functionate with less strain. Displacements and angulations of the intestines resulting from peritonitis, localized or more or less general, bear no relationship to any special clinical history, and each is a law unto itself; whereas the different disturbances connected with congenital membranes of the type under consideration all have a rather definite history, which can be recognized by the man of keen wits, and when the symptoms cannot be relieved by a careful study and regulation of the diet, and the use of a mechanical laxative such as paraffin, these cases become surgical. The last word has not been said as to the best technic to be followed in any individual case. Some of Mr. Lane's work appears too radical; among neurasthenics, I believe his technic of ileosigmoidostomy will sometimes fail if a catarrh of the mucomembranous type is present, unless there is added a fistula into the cecum for long-continued irrigation of the colon. In a paper which I had the honor to read before the Chicago Surgical Society, March 6, 1905, entitled "The Surgical Treatment of Chronic Mucomembranous and Ulcerative Colitis, with Special Reference to Technic," I advocated strongly the operation of Monprofit, in exclusion of the colon; it is known as "exclusion with drainage into the intestine," and is intended chiefly for obstructions in the colon. The ileum is divided far enough away from the ileocecal valve so that the divided ends can be implanted into the colon—the proximal end above, the distal end below, into the sigmoid or pelvic colon. In spite of theoretic objections to the contrary, the fluids from the excluded part of the colon drain through the ileocecal valve into the stump of the ileum, on into the sigmoid flexure. It would seem an improvement over this method of Monprofit's, if employed in chronic intestinal stasis, that instead of dividing the lower ileum, it be approximated to the sigmoid and two anastomosis openings made; between these openings the ileum should be occluded by a purse-string suture, and both limbs fastened to the sigmoid so as to close any opening that might permit of a loop of intestine becoming strangulated. In ileosigmoidostomy, reliance on Lane's last kink, congenital or artificially made, never appealed to me, because in this situation the intestinal wave is antiperistaltic, which was so beautifully demonstrated by Cannon years ago. This kink will hardly prevent a backward flow into the colon; if not competent to do this, the valve will dam back the accumulated feces above, since the *vis a tergo* and peristalsis have been removed by diverting the intestinal flow from the ileocecal valve.

---

* Read in the Section on Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

Where the cecum and sigmoid are sufficiently mobile, an anastomosis between them seems a practical solution and a relatively mild procedure. The paper above referred to as read in Chicago was based on my experience at that time, of eight cases operated on for chronic mucomembranous colitis. Four had a Gibson fistula made into the cecum for irrigation, and two had, in addition, the ileum divided, the lower segment occluded and the upper implanted into the sigmoid. One of my operations was after the technic of Maisonneuve. In these operations the appendix was removed, as the mucomembranous colitis was supposed to be secondary to a chronic appendicitis. My knowledge and recollections to-day tell me that the true reason of the inflammation was an intestinal stasis (our old-fashioned auto-intoxication), a Jonnesco-Reid genitomesenteric fold aggravating the difficulty. Removal of the colon is too hazardous an operation if an intestinal exclusion operation can be carried out in a successful way. The cecum, especially when not supported by a parietocolic membrane, may be large and mobile. In 30 per cent. of adult people with a large mobile cecum, symptoms referable to this condition are clinically present. The symptoms are present *not* because the cecum is large and mobile, *but* because its walls are flabby and it has lost the power of emptying itself properly. The condition is corrected by a plication operation, supporting the cecum or not, as indicated. The common ptoses of the transverse colon, sometimes into the pelvis, resulting from neglected function of the congenitally weakly supported viscus, are well handled after the technic of Coffey. As a rule most congenital membranes of the pericolic type are best released at their loosest line of attachment by passing some blunt instrument under the membrane along this line and dividing it. In other cases in which greater mobility seems desirable, the compressed intestine should be rotated toward the middle of the abdomen until a white line is observed on the posterior lateral wall of the abdomen, which is the line of fusion of the colonic peritoneum with the parietal peritoneum after rotation of the ascending colon has been completed. This is also the attachment of the pericolic membrane to the parietal peritoneum, and is the strongest line of attachment of this *ligament;* it should be divided along this line. This will give the greatest amount of motility and require the least amount of peritonization.

Wherever the membranes of the type under discussion are situated, if tension be made on the attached hollow viscus in a direction continuous with the course of the blood-vessels and fibers of the membrane, a white line will always be observed; this is the ligamentary attachment of the membrane to the parietal peritoneum, or to the peritoneal investment of a solid viscus.

In our citizenship, made up of a heterogeneous mixture, with "no thought for the morrow," like does not produce like in a possible totality. Sprouts, buds and offshoots appear in all grades of potentiality. Many more bodies are examined *in vivo* than in the deadhouse, giving better opportunities for comparison of the types of frequency of variations from supposed anatomic standards. The accumulating evidence offered by the study of the pathology of the living will make great strides in the recognition of normal anatomy before the end results of disease have obscured it.

I would like particularly to ask discussion on the following points:

1. If the Jonnesco-Jackson-Reid membranes are congenital, are they always more or less clearly demonstrable in every individual, should the incision admit?
2. Are the membranes purposive? If so, are they not intended by Nature as ligamentary supports—preventive of intestinal stasis rather than causative?
3. Therefore they should be divided only after they have become restrictive of intestinal function, from loss of nervous and muscular tone resulting from chronic intestinal toxemia.
4. Is the method of demonstrating the white line always reliable? If so, does not this in itself prove the congenital origin of the membrane and its physiologic importance?

3624 Dewey Avenue.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. EASTMAN AND SUMMERS

Dr. M. L. Harris, Chicago: For some time past I have been operating on a large percentage of my patients under nerve-blocking by means of some combination of novocain. Without going into a discussion of the advantages of local anesthesia over general anesthesia, I wish to call attention to the great advantage which local anesthesia has in affording opportunities in abdominal operations to demonstrate the origin of many symptoms which we have learned to recognize clinically, but which we have not always referred to the proper cause. After blocking the nerves of the abdominal wall and opening the abdomen, we may then reproduce, by a variety of procedures and manipulations, characteristic pains and thereby learn positively the cause of the particular pain in question. In operating in the region of the appendix it is easy to demonstrate that the appendix is insensible to any form of mechanical manipulation or injury. It may be crushed, incised amputated or cauterized and the patient gives no evidence of pain; but traction on the mesentery of the lower end of the ileum instantly produces the characteristic epigastric or umbilical pain of which many patients with chronic appendicitis complain. In the same way we can produce the sensation of nausea, and these patients can be made to gag and even vomit by certain manipulations of the mesentery about the appendix. We can reproduce the typical pains of inflammations of the other abdominal organs in this way. This is also true in cases of pericolic membrane of whatsoever nature. We can reproduce the same characteristic, general diffuse pains of which these patients complain, not by touching the pericolic membrane itself, because that is insensible, not by manipulation or making traction on the colon, which is likewise insensible, but by making traction on the membrane itself where it is attached to the parietal wall. This is true also of the gall-bladder and the stomach. What I wish to call attention to here is that the epigastric pain, the pain or sensation of nausea and vomiting, which is present in these chronic cases, is an intestinal pain, pure and simple. It is produced by injury to the nerves going through the mesentery. The diffuse pain, the general pain, is due to interference with the parietal nerves. In circumscribed adhesions the pain may be circumscribed, but it is due to involvement of the parietal peritoneum.

Dr. H. A. Royster, Raleigh, N. C.: Inasmuch as these papers have opened up the subject of peritoneal folds, I desire to call attention to what I think is an important addition to this question. Folds and kinks, membranes and veils, are the order of the day. So far those which have received names are on the right side. We have the Jackson veil, the Lane kink, and "cobwebs in the attic," but if we go farther and follow the large intestine around, we shall find that the splenic flexure gives us some trouble, and I wish particularly to mention the "sigmoid adhesion." Nowadays we think only of right-sided pain, or we try to account for the pain by finding something wrong in the right side of the abdomen. We do not know in any given case which adhesion is going to fit until we have opened the abdomen. I think that many of us are having a great deal of trouble to explain left-sided pain, particularly in the case of women patients, because the pelvis enters into consideration. My study was directed particularly to this subject of left-sided pain in women, and, on investigation, I found that the sigmoid played a tremendous rôle in these cases. The ovary was too often blamed for the trouble. When we opened the abdomen we found a condition which we did not suspect, and, more than that, one which we did not know at first how to deal with. The etiology does not bother us nearly so much as the solution. It does not matter much whether these pains are anatomic, physiologic or pathologic. They must be dealt with if they are causing symptoms. I would suggest, however, that these conditions, if pathologic, are simply exaggerations of an embryologic or a normal condition. The symptomatology of sigmoid adhesion is a rather negative one. An important point is that the patients complain of pain on the left side during defecation. They are more or less constipated, the constipation alternating with a mucous diarrhea in some cases. In women the question of pelvic pain enters largely into the consideration of the case, with or without the sigmoid adhesion. I have ready for publication a short paper dealing with this question and the methods of handling these adhesions. I first described it four years ago. It is merely a matter of cutting the adhesion across and then suturing in a longitudinal direction. This draws the sigmoid away from its abnormal or exaggerated normal position. This may explain many conditions on the right side; I have seen a distended large bowel due entirely to sigmoid adhesion, while lesions on the right side were not present. If you are considering these intestinal folds, look on the left side and you will find a distinct clinical entity which must be relieved.

Dr. A. A. Law, Minneapolis: I do not agree with Dr. Royster that we can ignore the etiology of membranous pericolitis. As scientific men we should investigate the etiology and attempt to solve it. It is a pity that we cannot all agree with Dr. Eastman's theories. I do not presume to advocate any one theory. We must give all the theories cognizance. If the embryonic theory is correct, why do we not find these membranes in children? I have never seen membranous pericolitis in a child. My youngest patient, and I reported thirty-one cases, was 18 years of age. This is significant, for it would seem that, with the large amount of abdominal surgery being done on children for other conditions, some observer would report finding membranous pericolitis. It is only after a mass of evidence has been presented and sifted that we shall be able to arrive at a definite conclusion. I have reported thirty-one cases of this pseudoperitoneal membrane and in every one roentgenographic studies were made after the ingestion of bismuth emulsion by mouth or its injection into the colon. This number of cases is, of course, too small to be of much value, but some of the points learned from the study are valuable. In every one of the cases there was cecal atony and ptosis. In every one the cecum was in the pelvis. If cecum mobile was not present at the time of operation, it was created when these membranous bands were released. Whether this is of significance, whether this ptosis of the cecum antedated the formation of the membrane or not, I do not know. In every instance except one, gall-stones or appendicitis was present. This would seem to confirm Gerster's and Pilcher's contention that the condition is due to a chronic poisoning secondary to fecal stasis in the cecum, for here with the dilated, atonic intestinal wall the musculature is unable to lift its fecal load over the hill of the hepatic flexure. This theory seems to me the most tenable.

Dr. D. N. Eisendrath, Chicago: There is absolutely no question that Jackson and Eastman have both made exceedingly valuable contributions to the subject. There is a pericolic membrane. Whether this membrane is of embryologic or acquired origin is an open question. I have come more and more to the conclusion, after observing a large number of cases clinically and making dissections not only on the human fetus but also on the dog and other animals, that this fold of Jonnesco is an embryologic structure which persists throughout life and which may give rise to conditions of undoubted pathologic significance. In about seventy laparotomies I have seen that this fold of Jonnesco is *not*, as Summers says, always identical with the colic mesentery. It is a separate membrane. In one of my cases the membrane passed across from the parietal wall of the peritoneum. It had the typical spiral twist and you could put a finger under the upper end of the membrane and lift it up separately from the colic mesentery. Since then I have observed it in a large number of patients who have not complained of any symptoms. On the other hand, I have operated on patients in whom this membrane caused a complete stenosis of the ascending colon. I think that there is no question but that this membrane is present in its embryonic form in almost every individual. Some surgeons may be impressed with the idea that Jackson's membrane is always a pathologic structure and strip it off violently, leaving many bleeding points. The patient will then surely have postoperative symptoms. There are a certain number of patients with chronic appendicitis who do not recover as we would wish them to do and these patients may have a Jackson membrane (fold of Jonnesco) which has undergone pathologic changes resulting in kinks or constrictions of the colon. Jackson and Summers both emphasized the point that one should not be content with a pin-hole incision, but should make an incision large enough to permit a good view of the entire ascending colon; then no pathologic condition which may be present and which otherwise may escape notice will be missed.

Dr. J. N. Jackson, Kansas City, Mo.: I have no fixed view as to the origin of these adhesions or bands; that is a point which awaits final determination. I have been amused to hear men say that this condition is congenital and therefore does not amount to anything. Doctors do not ignore a case of congenital club-foot, but try to remove this condition. Whether or not we regard the peritoneal fold as congenital, whether or not it is this fold which Dr. Eastman described, we know that it is a membrane holding down the intestine and that the one thing to do, therefore, is to make traction on the bowel and where the line shows sever the membrane and ligate the stumps to prevent a recurrence of adhesions when healing takes place. On the other hand, if the theory of Gerster is correct, that there is primarily a colitis and that the disease begins on the inside, the membrane should be cut in the same way and stripped off, because otherwise the condition cannot be cured and there is always the possibility of reproduction of the membrane. It is evident, then, that we must deal with the factor of the reproduction of that membrane. Hall's theory was that it was not a colitis, but a condition due to the passage of toxins through the bowel, which lifted the peritoneum and resulted in the formation of this membrane. If it be due to anything that started within the bowel, we must do something more than divide the membrane. We must make a cecal fistula, do an appendicostomy, a short-circuiting operation or a transposition of the cecum into the upper rectum; even though the ileum be shifted, this material will be brought back by antiperistalsis, which should be excluded; this procedure is therefore not always effective. The cecum has no membrane ordinarily that would cause a collection of gas and a distention of the bowel, and thus produce traction of the peritoneum which produces the symptoms which I described.

Dr. J. R. Eastman, Indianapolis: I agree in the main with what Dr. Law has said. He has an erroneous impression, however, as to my conception of the origin of pericecal membranes. I never have been so bold as to contend that the discovery of these folds in the fetus alone explains the origin of the adult pericolic membrane, or of Lane's kink. These ideas are submitted as evidence and not as established and complete proof. I did present three somewhat original conceptions, however, which I think are worth remembering as we proceed further with the study of this subject. If I were asked to state as briefly as possible the causation of the pericecal membrane I should write down "the fetal folds plus x," and make the "x" quite large. We believe the fetal folds to be factors. When one sees repeatedly in the fetus the adhesions between the caput coli and the mural serosa before cecal torsion through the arc of 180 degrees has taken place, when one sees it at a later stage somewhat more developed and again at still a later stage as a broad band of serosa, one cannot resist the impression that the fold is drawn out from the mural serosa by the internal rolling of the cecum. Again, when one sees so frequently in the fetus Reid's membrane or fold passing from the terminal ileum down into the pelvis, connecting the terminal ileum with the genital gland, one cannot resist the impression that this genitomesenteric fold bears some relationship to the anomalous bands seen in the adult, to which Mr. Lane has given the name of ileopelvic bands. Another point concerns the so-called bloodless fold of Treves. It is my conception that this membrane fuses with the caput coli and that many surgeons have seen it in the adult as a thin membrane tightly fitting over the caput coli and embracing the appendix. This thin fold, from which the appendix is often shelled by surgeons, is the persisting bloodless fold of Treves. It is frequently found in the fetus and no doubt often persists and is dealt with as an affair of adhesions during operations for so-called appendicitis.

Dr. J. E. Summers, Omaha: If Dr. Royster will read a recent monograph by Gray and Anderson of Glasgow, he will find his operation nicely illustrated and described. I said in my paper that, if you did not find peritoneal membranes of the pericolic type in the upper, lower or middle quadrants of the right abdomen, you would find them on the left side. By making traction you will find the white line in every person. By pulling on the sigmoid and drawing it toward the median line of the body, you will often find this white line. Dr. Law's cases are few in number and apparently he does not do much surgery on children. If you will examine a child's abdomen you will find the membranous bands there as often as you will find them in the adult. The only trouble is that they do not produce symptoms and are therefore overlooked. They are put there for purposes of support and produce no symptoms unless they cause angulation. If you do not look for them you will not see them, but they are there nevertheless in a considerable percentage of cases.

Operations for Stones in Bladder, Prostate or Urethra.—Steiner discusses the surgery of stones in the bladder, prostate and urethra in *Folia Urologica*, 1913, vii, 471. He gives the latest theories as to the pathogenesis of these stones but concludes that it can only be really determined by biochemical study of the intramolecular structure of the complicated combinations which form them. He gives in detail the indications for the technic of lithotrity and lithotomy, recommends von Hacker's suture for the bladder and emphasizes the importance of examining the kidney function before any bladder operation. He has performed litholapaxy in thirty cases, suprapubic lithotomy in fifty-five. Of the former twenty-eight patients were cured, of the latter fifty-two. Two deaths among the latter were to be attributed to a prostatectomy performed at the same time. He has besides performed three operations for stone of the prostate and seven for stone of the urethra. Eight of these patients recovered, the two deaths being due to uremia. Altogether he has done ninety-five operations for stone of the bladder, prostate or urethra with cure in 93 per cent. of the cases.

PRENEURASTHENIC AND PREINSANE CONDITIONS *

ROSS MOORE, A.B., M.D.
Assistant Professor of Nervous and Mental Diseases, University of California, Medical Department
LOS ANGELES

It is with a good deal of hesitation that I again present a subject on which I wrote two years ago. The longer I practice among the nervous and the insane, the stronger is the desire to have a hand in preventing their troubles rather than in curing them. The particular reason for this short paper is to bring out a full discussion of the question of prevention.

For a number of years when examining children I have tried to make up my mind as to what kind of adults they were to become. Results have been most disappointing in the main.

The disappointing thing was that I was not succeeding in finding, among children examined who were evidently not up to an average mental and nerve constitution, any classes or types of temperament to indicate their future neurologic or psychiatric dangers. To put it another way, after I had examined a given child, I found myself quite unable to tell the parents of that child what might be hanging over its head in the way of disease. This has been and is a woful lack. The parents knew and I knew that the child was not average. I am not now speaking of the high-grade idiot or imbecile or even of cases of much-retarded development, but of children who would pass for normal on casual observation, or who were considered as slightly queer. I lacked the knowledge which would allow me to say, "Your child has a temperament and constitution which is likely to make him insane or a neurasthenic in the future unless you understand him better and take such and such precautions." The parents had brought the child to me for expert recommendations as to their handling of it. They wanted something accurate and concise. My recommendations were diffuse because my basis for them was hazy. What I needed was a concrete notion of preneurasthenic and preinsane conditions in childhood, just as the tuberculosis expert has his clear idea of the pretuberculous habitus. No such concrete notion could be obtained from the literature at my command, so it had to be constructed. When an adult sufferer from neurasthenia or mental disease presented himself for examination, I went as far back as possible in his childhood history to determine his mental constitution and temperament before his illness asserted itself. I went to both pedagogic and pediatric literature for help.

The result has been the three loosely constructed types which I tried to delineate two years ago,[1] and to which I can add very little at present. My excuse for again presenting them is the importance of the prevention of nervous and mental disease in coming generations. They are not perfect. Perhaps there is no possibility of the general recognition of nervous and mental tendencies the same as we now detect tendencies toward tuberculosis. I want to know the opinion of the Section on this question.

There is at least one other reason for going over this ground again. There has been great activity in the matter of child hygiene among both laymen and the profession during the last few years. Men in general medicine, surgery, and eye, ear, nose and throat work have been studying along with teachers and school authorities to the end that abnormalities shall be corrected and future trouble averted. Over the world isolated specialists in neurology and psychiatry are also working. But, as a body, we are doing nothing so far as I know. Is it not time that we should officially record ourselves as trying to prevent as well as cure and relieve disease? To my way of thinking, this prevention can be based only on a better knowledge of child types—the soil on which, in later life, nervous and mental troubles develop. We must get this knowledge first and then we must pass it on to the men in general practice, to teachers, and to parents. The Section on Nervous and Mental Diseases of the American Medical Association is the logical fountain-head for this knowledge.

The three types I have begun to identify are as follows:

The Neurasthenic.—The neurasthenic adult is the logical result of a neurasthenic child or a normal child plus exhausting illness. Natural juvenile neurasthenia is clear-cut. On the physical side its symptoms are a general droopiness, poor standing balance, diminished expression of the face, and fatigue fulness or puffiness under the eyes. When arms are extended one will be held lower than the other and the thumbs will droop away from the rest of the poorly extended hands. Fingers twitch with irregular and slow motion, entirely unlike chorea, when the hands and arms are extended. An effort to stand erect causes an accentuated forward curve of the spine with a relaxed and protruding abdomen.

On the nerve side there is evidence of marked inability to accomplish, which is due to mental and not physical fatigue; an appearance of mental apathy which is not real, but is due to a queer combination of alertness with actual mental fatigue; a full appreciation of events and surroundings with a studied minimum of reactions to them, and abnormal sensibility to external impressions.

The Preemotional Type.—This type shades into and is often combined with the neurasthenic type. Children of the latter type, however, are usually well formed physically, while the preemotionals may show various physical stigmata frequently found with congenital mental disturbances.

The general distinguishing features between the emotional and the neurasthenic type are to be found in the study of the stimuli to which each type responds most readily. The young neurasthenic is seldom introspective. His stimuli are largely external. The future sufferer from mania, melancholia, hysteria, etc., responds to internal rather than external stimuli. Fear, ambition, love, hate, sorrow—all provide internal reasons for outward reactions, which at times become so prominent as to be labeled "unnatural." His existence is sthenic, not asthenic. He has a large range of interests and he keeps them all going. He is versatile and capable, intense in what he does and thinks, and vigorous in joy and sorrow.

The Predements.—These are the mental shut-ins. They are usually physically well built and admirable, while mentally "un-understood." Apparently happy and care-free, they often carry a hazy and terrifying knowledge of their own apartness from their associates. They are also characterized by a power to carry out their natural aptitudes with ordinary ability or even with brilliancy, thereby covering up defects in reasoning power which may be immense. They are not easily fatigued, not emotional in the usual way, seized by fundamental emotions and held by them because of inability to react to further stimuli; unable to correct ideas by reason and observation, unable either to understand or to explain themselves because of this flaw of intellect which makes impossible the exercise of sound judgment; consciously, uncomprehendingly handicapped.

[1] Moore, Ross: The Recognition of the Preneurasthenic and the Preinsane Condition in the Young, THE JOURNAL A. M. A., Dec. 23, 1911, p. 2079.

These are the three types. As described, the classification is very imperfect and possibly contains serious errors.

Fay Building.

ABSTRACT OF DISCUSSION

Dr. C. Eugene Riggs, St. Paul: The ultimate fact in this presentation is eugenics. Eugenics, like Banquo's ghost, "will not down." The child is the result of the forces of two ancestral strains. As one author has said, "Heritage is what we are, environment is what we have, training is what we do." Walter has described heritage as a method of reaction of the organism to the environment under which we live. The question is, Can this method of reaction be in any way modified? I believe that it can, Weismann to the contrary notwithstanding. Thompson cites the following instance: As the result of the inbreeding of two wheat plants, one subject to rust, the other immune, the hybrids were all subject to rust; but the inbreeding of these hybrids gave plants subject to rust and plants that were immune in the ratio of three to one. The surprising fact in this experiment, is this: that the plants that were immune to rust ever afterward bred true. This simply emphasizes a statement of Sir Thomas Clouston many years ago that there is an intrinsic tendency on the part of the individual to return to the normal. This tendency is not absolute, however. There is a certain class of defectives on which Nature has put her ban; I refer particularly to the feeble-minded. The nervous system makes its most rapid growth from the fourth to the seventh year. The brain of a child 7 years of age lacks but 2 ounces of the bulk and weight of the adult brain. The brain of a person 18 years of age has the full weight and bulk. Now, from birth until the child is 18 years old we have growth and development, and from 18 years to maturity, 25, we have development. In other words, before 25 we have the nervous system, like Kipling's ship, finding itself—coordinating itself, and bringing the whole organism into complete unity and harmony of action. Then again, from 12 upward we have the evolution of sex; also, somewhere about 14 we have the development of the intellectual, volitional and emotional faculties, the training of which means everything in the life of a child. Further, we know that if there is any weakness in the stock it will manifest itself during the adolescent period. It is at this time that dementia praecox and various forms of manic-depressive insanity develop. Thackeray, Goethe, John Stuart Mill, and many others, passed through a period of depression during adolescence. The important point is that if we can recognize those types which Dr. Moore has called to our attention, if we are aware of the dangers, the quicksands, in this period, can we not in some way prevent the cerebral and nervous disaster that otherwise will follow? Certainly we can in a proportion of cases.

Dr. G. H. Moody, San Antonio: We all realize the importance of recognizing early the weaknesses of children in order to anticipate what may develop later. As a general thing, however, I believe that we have a tendency to let the matter drop after our discussions are over, and consequently little has been accomplished. If Dr. Moore can continue and work out a tangible plan to be universally accepted whereby early in the life of the child certain tendencies can be recognized and placed in certain definite groups as he suggests, a great step forward will have been made. If he can keep under observation and follow them up for a few years those cases that he has been observing, he will secure some information that will be of great value and give us something more tangible in the way of classification than we have had heretofore. If by certain groupings which he has suggested we are able to know positively that a certain child belongs to a certain group, and is therefore in danger of developing neurasthenia if not properly guarded, that another will develop the insane complication, and so on, it would help us a great deal in a definite way. I think we are inclined right here to be a little too vague and indefinite in our attempt to do something for these children.

As suggested also, general practitioners should take up the subject, as well as teachers perhaps later. Much has appeared in recent literature regarding the dementia praecox type, which is simply a differentiation of types at a later age. Dr. Moore's proposition to start early in the proper training of these children is a most appropriate and practical one and will prove a valuable addition to the steps taken in handling these cases. If we will closely observe children with these tendencies we shall find that the symptoms manifested even at an early age are in many cases quite definite and readily recognized.

Dr. Philip Zenner, Cincinnati: So far as my experience goes I do not know that it would bear out Dr. Moore's ideas but, of course, we do not ordinarily have accurate knowledge of the early childhood of our patients. If further experience should bear out Dr. Moore's ideas, and we could in many cases foretell that this child will develop hysteria, this one melancholia, this one neurasthenia, and this one insanity, there is one great harm that might result from such knowledge. If, as has been suggested, we not only know, but also warn teachers and parents of the dangers that will come to that child, the child might be brought up with the knowledge that this danger is before it; and I can conceive of hardly anything worse for a child than to be brought up with the knowledge that he is in danger of and must be specially protected from neurasthenia, insanity, or the like. As I say, that is the one practical danger that might ensue from those ideas becoming more clearly outlined in our minds.

Dr. G. Wilse Robinson, Kansas City: Much can be done by the medical profession, and especially by this particular branch of the medical profession, in the direction pointed out by Dr. Moore. A great deal of good work is being done by school inspection in our cities relative to the physical condition of the children, but practically nothing is being done in the way of examining the mental condition of children in the major portion of our schools. Every city should have a laboratory in which these children could be tested and examined for the purpose of determining their mental condition. We cannot perhaps determine accurately whether the tendency is toward hysteria, melancholia, neurasthenia, or dementia praecox; but we can say that the children are atypical and can advise the parents that there are certain lines along which they can be developed properly—certain lines of study that they can safely pursue and certain lines of occupation that they can follow, while certain other lines of education and occupation they cannot follow. All education is simply the development of attentive control, and when these children develop neuroses and psychoses the cure of these conditions usually resolves itself into education of attentive control. With proper development they will become useful citizens, while improper training makes them public charges.

Dr. L. Harrison Mettler, Chicago: I should like to speak a word of caution on this important subject. The title of Dr. Moore's paper reads "Further Notes on the Preneurasthenic and Preinsane Conditions." I do not suppose any of us will question the desirability of the closest study and careful management of the distinctly pathologic types of these conditions. My suggestion is that, in our pedagogic enthusiasm, we must be careful not to go too far and regard individuals as defective who do not conform to our personal standard of normality. There is a great and serious danger of this among the mild or border-land cases. In the history of the world, the originators of ideas and the instigators of progress have been people who were regarded as being a little "off" in their day. The development of civilization and human advancement are not primarily due to the average, so-called normal, man. The latter is rather conservative and does his part in holding things steady or in preventing retrogression. To the average, normal man, so called, new ideas seem strange, erratic and abnormal. He who brings forth these new ideas is usually atypical as an adult, and may have been atypical as a child; and it is an exceedingly difficult matter at times to differentiate an individual who is atypical merely in a sociologic sense from one who is atypical in a pathologic sense. Our whole system of public education is evidence of this. Sometimes it were better to let some of these apparently atypical children develop in their own way both for their own good and the good of the world. A dull, uniform mediocrity is not the goal of the human race.

Much here depends on the ability of the examiner. As in meddlesome midwifery, so here there is more danger of too much unintelligent interference than there would be in no interference at all. It may happen that a medical examiner's standard of ability may be quite below that set by the child for itself. The art-loving child may appear to be quite peculiar to the mere card-playing doctor. Again, children are sometimes rendered neurasthenic and hysteroid by their environment and stupid parents. Though the child may here appear to be atypical, it is the environment that is atypical for the child. Someone has well said that if half of the children were dismissed from the public schools and their places taken by their parents, a great improvement would be seen in the child-life of our nation, and, I am sure, much smaller number of atypical children would be met.

Eugenics is teaching us much nowadays. The science is still in its infancy. We must not dogmatize beyond the facts in hand. We must, as individuals and as a profession, learn more what mental health means for a given child and not adopt any fast and set standard, based merely on average mediocrity. This is a large task.

Dr. W. W. Graves, St. Louis: Some one has said that in Nature there is no blind tendency toward perfection, and it seems to me that if we recognize and study types in a comparative way, eventually we shall be able to secure not only definite data by which we may recognize the tendencies of individuals and prevent disasters in their lives, but also information which may be applied in the begetting of offspring in a eugenic way. Let one go into a home for the feeble-minded, into an epileptic colony, or into an asylum for the insane if he will, and there he will meet with essentially different types of humanity from those which he meets in the common walks of life. More than that, if one studies in a comparative way the parents of the feeble-minded, of the epileptic and of the insane, and the near relative, he will often find similar types. The insane, the feeble-minded, the epileptic, are persons whose resistance to disease is inherently lowered; they are unable to adapt themselves to environment, and they succumb relatively early in life. If we can by the study of types learn to recognize what is the underlying factor in disease, if we can determine what are the factors in the life of the individual that cause him to be less resistant in the stress and strain of ordinary existence and make him peculiarly susceptible to disease, this will help solve the problem. We must soon recognize the necessity of studying human beings from the biologic point of view. The only conceivable fact underlying every function, whether it be mental, physical, or what not, is that without structure, function is not thinkable. We must therefore study human beings with the same sort of ideals that we study the plants or animals or any other living thing in Nature. While we have no such condition as normal for any living thing, we have ideals of normality, and those ideals are founded on harmony of structure, proportion of structure, and adaptation of structure to function. These factors enter into the point of view from which we should judge human beings. There is an old classical ideal, *Mens sana in corpore sano.* Persons who fulfil this ideal represent the good types of the race, types which we seldom find in insane asylums. Instead we find the abnormal types representing asymmetries, disproportion and disharmonies in development. If we study human beings as we study animals and look for the points of the ideal in their physical make-up, we shall have at once some basis for the determination of the resistances of the individual, not only to neurotic disorders, but also to disease in general.

Dr. Howell T. Pershing, Denver: We have two things to consider here. First, the general scientific facts concerning nervous children, and, second, the tremendously difficult problem of the individual nervous child. It seems to me that most of our work has to be done with the individual, and with him alone. There is a great barrier, as a rule, between the child and his elders. The height and thickness of the stone wall that sometimes separates father and son render it almost insurmountable. The average nervous child is a lonely child. He plays with his fellows, goes to school and talks with his elders, but there is much going on in his mind which he keeps to himself that would be important for his father or the doctor to know. All our conventions tend to repress self-revelation. In being educated into ordinary decency and morals, a child gets a terror of mentioning certain things. He is not going to lay bare his mind before any one, not even his father or mother. It would be a great advantage if to the proper extent we could establish communication between a wise elder—a *wise* one and not any one that happens to be in the schoolroom—and a sensitive, nervous child. With all this, we must respect the personality of the individual. There is a certain amount of reserve that ought not to be broken down. How far shall we go in getting into each individual's own mystery? And in it all we have to be exceedingly careful not to implant any morbid fears in the mind of a child. We must be careful not to give the nervous mother an idea that her child is going to be insane or even a neurasthenic, as Dr. Moore has said. This is an extremely difficult matter to deal with. I remember reading long ago a short story by Hawthorne which ended tragically, and, as I recall, the last sentence read something like this: "He had taken the delicate soul of a woman into his rude hands and crushed it." It is easy to take the delicate soul of a child into rude hands and crush it. It is easy to instill into the mind of a child ideas which will act as a veritable poison, and yet there may be ideas already acting as a poison which could be removed if the right person knew of them. So I try to encourage my youthful patients to feel that it is proper and safe to tell me of anything that troubles them in order that I may be able to help them. It is, however, a difficult matter at best.

Dr. C. B. Woodson, St. Joseph, Mo.: Children of the types under discussion should be dealt with not unlike others. To point out that a child is nervous, sending a note to mother or teacher to this effect with suggestions as to care, etc., is simply being meddlesome. The matter should be presented systematically to the parent; it is not necessary to say to the parent that the child will not develop into a strong individual mentally. The important thing for any child is to have good sanitary surroundings, proper nourishment, and a reasonable amount of exercise and play. All children should be taught the importance of bearing disappointment well. If the child goes into a rage because it cannot do the thing it wants to do, it makes no difference whether the condition is one of prenervousness or not, it gets the better of that child. Study along lines of special aptitude is perhaps one of the worst things that can be carried out, either in the case of a nervous person or one who is not nervous.

There is no reason why the offspring of a person suffering from a pronounced neurotic taint or history should become insane or be particularly nervous, if the right lines of education are followed out; but the individual who has this tendency or predisposition should not go into a business that would carry with it, for him, a hazard, for this would be sure to cause the development of depression and anxiety. He should be kept on safe ground. When we come to overloading, however, it matters not who it is, I maintain that when the load passes beyond the resisting capacity we can put on enough to crush the individual. Load the horse, the bridge, the wagon, the elevator, beyond resisting capacity, and the structure must be relieved or there will be a catastrophe. The best thing to do in these cases is to establish close relationship of the parent if he is normal. If the parent is not normal it is better not to have this companionship. If the parent is so easily startled that the child tends to become timid, this makes the child nervous. If the parent is overexacting this makes the child nervous, although the parent is unconscious of it.

A liberal education regarding matters in general, in school, in business, in dealing with associates, etc., should be maintained as much as possible, and to overcome defects in the child it is highly important for the teacher to cooperate with the doctor to this end.

Dr. Ross Moore, Los Angeles: The men in general medicine, or those making a special study of tuberculosis, are in a position to say that such and such things really constitute a habitus which predisposes a child to tuberculosis in the future. They can make a clear word-picture of this habitus. Their discussion would not have gone far afield, because there are certain definite ideas in their minds as to what constitutes a pretuberculous condition. A parallel to this is the gist of what it was my desire to bring before you in this paper. Instead of that, we have in the discussion reached a number of different points of view. The discussion indicates the state of mind which is present among neurologists and psychiatrists on the question of preneurasthenic and preinsane conditions. I am inclined to believe that the types which I have tried to delineate are inaccurate. They must be, because they are based on too small evidence. And yet the discussion has been sufficient to make me believe that something along this line might be done if we all went at it in the right way. The subject is a good deal wider than the paper. I wish not only to recognize these things to prevent disease in the future, but also to widen out the question of eugenics to the end that people who are peculiar in these ways will learn not to marry, or, at least, not to have children.

Nature would be a good mother, it is true, if only Nature could have the chance. In these days, however, Nature is so badly modified by what we call civilization, that we neurologists and psychiatrists really have a big field in which to help this good old mother. Interference, of course, which creates panic in the hearts and minds of parents is wrong. If, however—the doctor knows absolutely before he says anything to the parents at all that a child ought to go along such and such a line in his future development—then he has a basis in his own mind for a wise, just, kind, and thoroughly helpful recommendation to the parents.

Most of the adverse discussion which we have had here more or less revolves around the idea of our not doing the right thing by these children and by the parents. The reason that we cannot do it is simply that we have not the basis for it. Yesterday we found distributed here a notice from Buffalo inviting all the world to attend a meeting there in August which will deal with the welfare and instruction of children. A few days before I left home communication came to me through the mails giving the names of men all over the world who are particularly interested in this movement toward child hygiene. I was sorry to find few neurologists and psychiatrists among the number.

Compulsory Cleansing of Milk Receptacles.—According to the April *Bulletin of the Indiana State Board of Health*, a law was enacted by the last legislature of that state requiring the cleansing of milk-cans, bottles, etc., immediately after the removal of the milk therefrom. A similar law enacted in New York was upheld by the Supreme Court of the state, after being attacked on constitutional grounds. The court held that on account of the danger to be apprehended from the use of unclean receptacles for milk intended for human food, drastic measures to prevent the possibility of such use are reasonable and justified, and that it is clearly within the police power of the state to require dealers to wash bottles before they are refilled. With this precedent the Indiana law will probably not be attacked on constitutional grounds. It is a proper and reasonable regulation.

TEACHER AND LEARNER IN MEDICINE*

FREDERICK H. PRATT, A.M., M.D.
Professor of Physiology, Medical Department, University of Buffalo
BUFFALO, N. Y.

We are to-day in the midst of a great unrest in American medical education, and the movement for a true teaching spirit in medicine is now irresistible. How shall we meet it, how help it on its course? I propose to assemble what seem to be the chief factors in our problem as teachers and learners, setting aside formal administrative questions, and dealing largely with the more personal and fundamental. Let us try, on the threshold of a new year of work, to catch this true spirit, in order that it may permeate all our coming endeavors.

In reviewing the experience of a student of twenty, fifteen, or even ten years ago, one is forced to wonder that medical teaching has lagged so far behind medical knowledge. When Vesalius struck down the centuries-old authority of Galen, and made anatomy a fabric of thought and action, he surely laid therewith the foundation of an effective mode of teaching and learning medicine. But such it was not to continue. Medicine germinated, and blossomed finally with Pasteur into a science. Medical teaching meanwhile wrapped itself in its medieval cloak, and for generations the student sat passive in the lecture room while the professor droned.

THE LECTURE AND PASSIVE RECEPTIVITY

The lecture method may in fact be used to furnish the key to the situation. We learn to see by seeing; to think, by thinking; to do, by doing. The plan in the old-time medical school was briefly this: the professor, having in the richness of his experience seen, thought and done, appeared before his students and told them things, often interesting, sometimes not. It was this passive reception of information about the work of others that gave validity to the student's degree. Yet not for a moment was it conceded that the lectures prepared the student to practice medicine. The student learned to practice medicine by *practice* in the old days, under the supervision of some one experienced physician; in later years, in the laboratory and clinic. All this has now become so clearly seen that we must accept the conclusion of Le Count[1] that "a medical school should be a place where medicine is practiced by students instead of a place where students prepare to practice." "These things," he says again, "are learned not by the telling but by the doing."

We do not need to confine ourselves to writers on medical education to find expression of the principles that should guide us. Reform is wide-spread, and some of the most telling and acceptable criticisms for us that I have met are from university and college teachers of other subjects. Nothing could come more directly home to us than the following comments of Alexander Smith[2] in connection with chemistry teaching:

> The lecture places the student in a passive and receptive attitude. Yet it is not the reception, but the reproduction of an idea that fixes it on the memory. The hearing of a story makes no permanent impression. It is only after we have retold the story that it suddenly leaps into a permanent position in our repertoire. The first hearing of an idea pro-

> duces but a faint track in the brain. It is the putting together of this idea, in its original setting, and also along with new ideas, that converts the first faint track into a traveled road. Is it not one of the strong points of language study that the student must put together in an endless variety of forms, the limited number of ideas he is trying to master, and must do this by his own efforts? . . . If we had attempted to devise some method which should run contrary to all conditions for successful undergraduate instruction, we could hardly have invented a scheme which would be more certain to fail than that I am discussing. The main point is that we learn only by our own efforts, and not by watching the efforts of others. Some one has said that the college is a "gymnasium where the faculties of men are exercised and developed, rather than a boarding-house where the students are crammed with facts." We develop physical muscle by exercise. Is there any other way of developing mental fiber? Can we ever cause mental fiber to *develop* by dealing out ready-made ideas? It is a psychologically impossible process. . . . Let us beware of a method of instruction in which the facts are found, not by the student, but by the professor; in which they are arranged and related, again by the professor; in which the conclusions are drawn, by the professor; and the conclusions are finally tested, not by the student, but by the instructor.

I was interested some years ago in noting the student's attitude toward medical lecture courses, and found that the student, with his usual ingenuity, had devised various means of circumventing an admittedly useless demand on his time and patience. Of course, the problem was to pass the examination. There were various ways of doing it. Only one of these ways was to attend lectures and use one's own notes. Printed notes could be bought, often better than one's own. Notes could be borrowed. A "quiz-class" could be attended, where direct contact with a tutor lent a certain real value to the instruction. Rarely were accredited textbooks employed, though the miserly but handy "compend" often did its share. The men passed, often well. Some got highest marks without even knowing the instructor by sight. Passing in itself had become a finely specialized art. In a discussion of the lecture method undertaken at that time[3] I wrote as follows:

> A system which thus encourages the art of passing must create for the student the delusion of a royal road. Moreover, the austerity of the informative lecture is not the austerity which develops effort, but is rather indulgence cloaked with severity; and the result is a form of parasitism. Lectures covering a subject in detail are the outcome of extended study and compilation on the part of the instructor; he gathers, systematizes and places at the disposal of his students what he thinks they need to know. It is food elaborated by professorial industry, found all-sufficient by the student and taken exclusively as a matter of economy. The student parasite adapts himself readily to this predigested diet: organs of independent acquisition disappear, being useless, while organs for appropriating the elaborated food develop prodigiously; and the process is consummated in the complete acquirement of the art of passing. No matter how much hard, self-denying work is done on material obtained wholly from lectures, the weakness remains. The student comes to regard the lecture as the source of all knowledge; and the apparent all-sufficiency of lecture information, emphasized by examination, deters him from independent effort. By avoiding certain subjects a student may complete a college career almost without once entering the library. He has never learned even the meaning of original sources and is consequently devoid of the power which their use alone can impart. As a lecture parasite he thrives as long as lectures thrive, and at the end has earned his merited reward—a surfeit of information; but the faculty whereby alone information is of any worth is rudimentary or wanting. Students taught chiefly by lecture become effectively trained in but one subject—the passing of examinations. As Huxley said, "They work to pass, not to know; and outraged Science takes her revenge. They do pass, and they don't know."

What Huxley[4] said in 1874 could be said in this country of most of our best medical schools in 1900, and is still true of any institution at which the student is fed, as Osborn[5] has expressed it, on "mental peptones." "The measure of a teacher's success," he remarks, "is the degree in which ideas come not from him, but from his pupils," thus summing up the main contention of his master, Huxley.

Let us not make the mistake of condemning the lecture because it has given us ill return for the sort of use we have made of it. It is not lectures *per se* that we must abolish, but a certain educational fallacy, already indicated, to which the lecture method has proved the easiest prey. Knowledge that is power cannot be gained by passive, sponge-like receptivity.

"Knowledge by suffering entereth." Knowledge is a strife. Hence the motto of our new teaching is one entirely inconsistent with merely informative instruction. It is well put by Jackson[6] in these words:

> Never tell a student anything he can observe for himself; never draw a conclusion or solve a problem which he can be led to reason out for himself, and never do anything for him that he can do for himself.

CHARACTERISTICS OF GOOD TEACHING

The legitimate uses of the lecture are many and valuable. Get the student to seeing, thinking and doing for himself, and you have in the lecture-room a rare opportunity to give direction and unity to his work, and to impart stimulus—perhaps inspiration. The lecture, relieved of its undeserved incubus, takes its place as a useful adjunct.

Let it be remembered that there is not a single method of teaching that we can employ into which the fallacy of passive receptivity cannot in one form or another find entrance. If laboratory experiments are followed by rule of thumb—mere tasks for the hand and the note-book; if dissections are made as perfunctory demonstrations of memorized pages of anatomy; if the clinic is "attended" merely, instead of being *used;* if treatments are prescribed as inevitable sequences to given diagnoses—if any or all of our vaunted methods of "practical" instruction lack that reasoning, problem-solving strife for knowledge that alone begets the faculty to do, to do well, and to win—we are still harboring the insidious infection that we sought to exterminate when we burned or otherwise sterilized the lecture system. I once overheard one student ask another, in one of the best courses in pathologic histology given at that time in this country, "What are we required to see?" That student expressed in six words all the blindness of the middle ages and the arch-heresy of modern science. If a student has ever looked into his microscope and wondered what he was "required to see," let us hope that he may have changed his mental attitude when, as physician, he looks into his patient's throat.

This case is paralleled by one cited several years ago by A. A. Noyes of the Massachusetts Institute of Technology in his admirable "Talk on Teaching."[7] The student came to his instructor "with the complaint that he couldn't do his problems because each one was different from the others." I am glad that he was not a medical student. "The good teacher is constantly trying to lead the student on," says Noyes, "but he refuses to carry him."

F. S. Lee[8] takes exception thus to a recently published laboratory manual of physiology:

> The most striking feature of the book is the elaborateness of the directions for laboratory work, *something with which we in America are not familiar.* The student is never left to determine a procedure for himself, but is told exactly how to do the thing desired. He must, for example, hold his scalpel thus and so, the verbal instructions being supplemented by a nearly life-sized picture of a hand holding the instrument. . . . In order to tell how to make a frog's muscle-nerve preparation two pages of text are required and two additional pages of life-sized illustrations.

Lee concludes his review with the following quotation from one of the Carnegie reports:

> *If, then, physiology is to be taught as an experimental science, as a science of function, the student must be allowed to run risks, to calculate, to observe, to verify, to conclude. Eliminate risk and the experiment becomes a mechanical toy: may amuse, it does not discipline.*

have referred to "A Talk on Teaching" by a professor of chemistry.[7] It is full of valuable advice, directly applicable to our own teaching problems. Of somewhat broader scope is George Herbert Palmer's "Ideal Teacher." Palmer[9] has outlined in a fundamental, simple way his conception of the good teacher. What most concerns us, I think, is this: The prime, imperative condition to be fulfilled by the good teacher —in fact, by any one worthy to be called teacher—is that he love to teach. Here is a passage worth much quoting:

> Harvard College pays me for doing what I would gladly pay it for allowing me to do. No professional man, then, thinks of giving according to measure. Once engaged, he gives his best, gives his personal interest, himself. His heart is in his work, and for this no equivalent is possible: what is accepted is in the nature of a fee, gratuity, or consideration, which enables him who receives it to maintain a certain expected mode of life. The real payment is in the work itself, this and the chance to join with other members of the profession in guiding and enlarging the sphere of its activities.

I am convinced that, no matter how important methods and policies may be in our medical teaching, a rich source of our failure lies in the assumption of instruction by those who do not in their hearts love to teach. A man may be an atrocious lecturer; he may be slow, awkward, outwardly uninteresting. If he loves his subject well enough to know it, and in addition loves to impart it, somehow he can kindle the student and get work out of him when the more facile man fails.

EXTERNALS AND INTERNALS

Just as the externals of manner and method count but little beside the spirit and motive within the man, so do the externals of housing, equipment and appropriation fall more than into second place when we consider the man and his subject. Some one asked an eminent teacher what he would regard as requisite in order to establish in a certain institution a department of psychology. His reply was to the effect that, first, a *psychologist* was necessary, and then, if one wished, there might be provided some bits of colored paper—though the latter were comparatively unessential. "We put our trust too much in systems and not enough in persons," says our authority on botanical teaching, William Francis Ganong.[10]

> And for this there are many evidences. For one thing we rely too much on a supposed virtue in buildings and equipment, though in this we but share the spirit of our machinery-mad day and generation. It is much easier for us Americans to obtain great laboratories and fine equipment than to make good use of them afterward, and nowhere among us do I see any signs of a Spartan pride in attaining great results with a meager equipment. Moreover, we make a deficiency of equipment an excuse for doing nothing. As one of the most brilliant of American botanists once said, some persons think they can do nothing in the laboratory unless provided with an array of staining fluids which would make the rainbow blush for its poverty.

Given teachers who love their subject and take joy in teaching it, who know their subject so that they can give lavishly, who can so interpret the mind of the student that the subject may incorporate itself effectively in relation to other subjects, and who insist on learning by doing, and doing well—and what matters it if the rooms be dingy and the bottles cracked?

For the student, too, externals count for little. Says David Starr Jordan:[11]

> The man, the teacher and the contact with Nature—these are the only realities . . . The university cannot make the man . . . its principal influence is found in the degree to which it grants the inspiration of personality.

The student entering his professional course should remember this: "The university cannot make the man." It can put nothing into him that is not already there in some form. It is for him to see that what *is* there receives exercise and development. It is he who does the work. If he has in him a living desire to make the most of his opportunities, a liberal education in the best sense awaits him. "Any study is liberal," in the words of Tufts,[12] "if pursued in a scientific manner and given significance for human life. Such studies call out a widening self. In such studies the mind comes to its own. In such it gains power." "Medicine," he adds, "is perhaps the farthest advanced of the professions in this respect." This judgment, coming from a non-medical educator, is for us significant.

AIMS FOR THE STUDENT

The student must not be content to follow solely the path marked out for him in his course. He must enrich his mind, while it is yet plastic, with general reading that is good, if ever so little. No one needs broad interests more than does the physician. He may have to fight hard to get these things, but they are worth the fighting. "Without idealism of purpose," said Christian A. Herter,[13] "without the willingness to make sacrifices of material comfort and much that the world overprizes, the career of the student and practitioner of medicine is almost certain to be pitifully limited and mediocre."

The possession of keen, responsive senses is a priceless asset to the physician, and this will depend not only on his general bodily health, but also on such foresight and sacrifice as are necessary to maintain a life of self-control. "The careful preservation of the senses in the freshness of their perfection," wrote Philip Gilbert Hamerton,[14] is altogether incompatible with every species of excess."

> If you are to see clearly all your life, you must not sacrifice eyesight by overstraining it; and the same law of moderation is the condition of preserving every other faculty. I want you to know the exquisite taste of common dry bread; to enjoy the perfume of a larch wood at a distance; to feel delight when a sea-wave dashes over you. I want your eye to be so sensitive that it shall discern the faintest tones of a gray cloud, and yet so strong that it shall bear to gaze on a white one in the dazzling glory of sunshine. I would have your hearing sharp enough to detect the music of the spheres, if it were but audible, and yet your nervous system robust enough to endure the shock of the guns on an ironclad. To have and keep these powers we need a firmness of self-government that is rare.

Two qualities I would urge the student to cultivate in relation to his work. They are patience and loyalty. Often he will feel disposed to grumble because he cannot see why such and such a subject is dragged into a medical course, or why he need learn the details of a yet unsettled problem in science. Let him have patience, remembering that subjects possessing apparently a very indirect bearing on practical medicine have been and always may be of deepest significance. The judicial mind is one of the highest possessions of the physician; and loyalty, of the friend and gentleman.

WORK OF THE PHYSICIAN

It is an oft-repeated truism that the doctor should be what his name implies. Yet it cannot be too earnestly reiterated. Few men are called on to teach more things than is the doctor. His influence over the community is enormous. He must train himself to render service wherever possible in teaching people to live sanely.

He must also teach them to *think* sanely. The public mind is wofully ignorant of what medical science is, and of what it has done and can do for humanity. Swayed hither and thither by charlatans, agitators and an undiscriminating press, the public instinctively seeks the doctor as the one fitted to expound the sober truth and point out where authority really lies. He cannot begin too soon to practice the weighing of scientific evidence, in order that he may spread the new gospel in medicine—that demonstrated facts, not philosophies and schools of opinion, are now in medicine, as they have long been in the natural sciences, the sole basis of practical application. Through such endeavor alone, which I hold to be the very highest that can claim the attention of the physician, can come that movement for public sanity characterized by President Eliot[15] as a "new Declaration of Independence," which, he says, "would exhort the people to spend more money on public education, so that the new generations may become quick to detect error, to accept facts and to discriminate between the plausible and the sound, the probable and the improbable, the credible and the incredible, the guesses of a roving imagination and the results of actual experiment." Lee[16] has called the physician who is also a good citizen "a missionary of common sense."

THE MAN OF SCIENCE

What an overworked, distorted expression "scientific" is in every-day life! It has received such advertisement for commercial and sensational ends that we cannot speak of science without suggesting a sort of wizardry, through which astonishing discoveries occasionally emerge from absent-minded, cold-blooded, impractical gentlemen in laboratories, whose time is mainly spent in satisfying a prying curiosity. From the time of Galileo to this day it has been the lot of science to be misinterpreted and misunderstood. It does not take the medical student long to begin to see how utterly medicine draws its sustenance from abstract science; and who shall bring the public into helpful, sympathetic relation with the scientific investigator but the physician, who owes his hourly skill to the truth-seeking labors of Harvey, Bernard, Helmholtz and Pasteur? The work of science is simply *an attempt to arrive at truth through honest observation and straight thinking*. And it is the duty and privilege of the physician to proclaim it as such; for, in the noble words of Huxley's autobiography,[17] "there is no alleviation for the sufferings of mankind except veracity of thought and action."

Beyond and above every triumph of applied science that brings a boon to humanity there hovers a great cloud of witnesses—names known and illustrious, names unknown or forgotten in the theoretical, "impractical" realms of learning—to whose labors the final inventor or discoverer has added his final straw of genius. We must teach the people to reverence such names as they are reverenced, for example, in France and Germany. When the French people voted to see who was considered their greatest man, it was not Napoleon who was chosen, but Pasteur, whose unspeakable service had won their love and gratitude. To this end every medical man should be a reader of scientific biography. The final triumph of truth attained is dramatic and inspiring; the path of action marked out thereby, clear and satisfying. Thus in the midst of his baffling problems the physician can take heart, and likewise help others to take heart, in the thought that life-giving knowledge is replacing, little by little, the ignorance of the ages.

[17] Huxley: Method and Results, Essays.

Duration of Infectiousness of Secretions in Epidemic Poliomyelitis.—Kling, Wernstedt and Pettersson state that in a series of nine cases of typical infantile paralysis the secretions from the mouth and intestines were obtained by lavage, and monkeys were inoculated with them after various intervals. In their communication on the subject in the *Zeitschrift für Immunitätsforschung*, 1913, xvi, 17, tables are given showing the results obtained at periods varying from one week up to seven months. Almost all the monkeys inoculated in the first few weeks died; only one died after a lapse of seven months. In only one case were the secretions harmless as early as by the end of the first month. However there was a steady decrease in the degree of virulence manifested. Inflammatory exudate in the spinal cord was found only in cases inoculated during the first two or three weeks. After that the chief change was degeneration of the nerve cells, showing diminished virulence of the toxin. It would manifestly be impossible to isolate patients for the several months during which the secretions are infectious, but if they are isolated during the first few weeks of greatest virulence the disease will appear only in the milder or abortive forms.

THE CLINICAL AND PATHOLOGIC RELATIONSHIPS OF HYPERPLASTIC AND NON-HYPERPLASTIC GOITER *

H. S. PLUMMER, M.D.
ROCHESTER, MINN.

The study of the clinical and pathologic relationships of the various types of goiter has of necessity been followed with the greatest interest in the surgical clinics. In a short paper it is impossible to review the various contributions to the subject. The following points, however, may be selected from the work done in these clinics: the clinical classification of the cases of goiter into simple or exophthalmic or equivalent terms, and the pathologic classification of the thyroids removed at operation into those with and those without sufficient hyperplastic or hypertrophic changes to characterize the gland; the recognition of toxic-goiter heart in a certain percentage of cases that are not diagnosed exophthalmic goiter and a less generally well-defined idea that the cardiac damage is only one of the manifestations of a general toxicosis; the finding of hyperplastic changes in from 70 to 90 per cent. of the thyroids removed for exophthalmic goiter, and the occasional presence of hyperplasia in glands removed from patients not having a history of notable toxic symptoms. Wilson, in 1908, after reviewing the available pathologic material from the cases which had been diagnosed as exophthalmic goiter, and in which operation had been done at St. Mary's Hospital, pointed out that 80 per cent. of the glands showed hyperplastic changes, and that, in general, the length and severity of the case history could be determined from the pathologic findings.

The relative constancy of notable hyperplasia in the thyroids of fully developed exophthalmic goiter, contrasted with the occasional failure to find this pathologic condition in glands removed from patients having an apparently similar clinical picture of this disease, and the rare finding of diffuse hyperplasia without accompanying evidence of thyrotoxicosis has led to much discussion and conflicting opinion regarding the specificity of this change.

In the latter part of 1908 a review of the clinical histories and the pathologic reports of our entire series listed as simple and exophthalmic goiters led me to the following conclusions: 1. We have at least two distinct, but very similar, types of thyroid intoxication, one associated with non-hyperplastic goiter, the other associated with hyperplastic or hypertrophic thyroids. 2. All cases having thyrotoxic symptoms with notable hyperplastic thyroids should be diagnosed exophthalmic goiter and that cases having thyrotoxic symptoms without notable hyperplastic thyroids should be classified with the cases of toxic-goiter heart, at least until we have still further evidence on which to subdivide these groups.

The main objection to these conclusions was the inability to make the clinical and pathologic diagnoses agree in about 10 per cent. of the cases. The lack of constancy in the clinical and pathologic relationship in mild and atypical cases could be easily explained. Our series, however, included (and I think this was true in other clinics) a number of cases of apparently typical exophthalmic goiter with exophthalmos and a pathologic report of adenoma, colloid goiter, adenomatosis, etc., without hyperplasia. A careful study of these cases demonstrated errors either in noting the presence of exophthalmos or from incomplete pathologic examination in the majority of instances and a probability of errors in the remaining portion.

This led to the use, in writing the histories of the 3,207 cases that have come to operation since Jan. 1, 1909, of forms covering in great detail the points which might later prove of use in studying the development and course of thyrotoxicosis and its relation to the pathologic changes in the thyroid. Figures and signs having, so far as possible, fixed values have been used in place of descriptive adjectives. Observations of fact and opinion have been carefully distinguished. The clinical and pathologic findings have been placed in parallel columns without any comparison of notes on the part of the clinicians and the pathologists. Clinical records for statistical purposes have not been changed after the patient came to operation. This has made possible the compilation of statistics by clerks who are not in any way warped by preconceived ideas or a knowledge of factors other than those under immediate consideration.

Correlating the statistical data, we may safely come to the conclusion that exophthalmic goiter is a definite clinical complex always associated with hyperplasia of the thyroid, and that it should be sharply distinguished from the constitutional state or states that may develop with non-hyperplastic goiter. As a complete review of this material is beyond the scope of a short paper and the patience of the average reader, I have attempted to answer the questions brought up with the least possible amount of statistical data, using only the following factors: the age at which the goiter is first noticed by the patient; the age at which thyrotoxic symptoms developed; the presence or absence of exophthalmos, and the presence or absence of notable hyperplasia in the thyroid. It is my purpose to take up these questions with a full report in a series of papers.

The term "thyrotoxicosis" is here applied to the constitutional state associated with goiter. As a matter of convenience for quickly presenting the association of the clinical and pathologic findings, the constitutional symptoms accompanying goiter have been attributed to a toxemia the result of a disturbed thyroid function. As a temporary expedient the cases have been classified pathologically as hyperplastic and non-hyperplastic, and clinically as hyperplastic-toxic, hyperplastic-atoxic, non-hyperplastic-toxic and non-hyperplastic-atoxic. The glands showing marked hypertrophy have been included with the hyperplastic goiters. Following this classification for the 2,917 new cases coming to operation between Jan. 1, 1909 and Jan. 1, 1913, 42.8 per cent. are hyperplastic and 57.2 per cent. are non-hyperplastic. Of the hyperplastics 99.2 per cent. are toxic and 0.8 per cent. are atoxic. Of the non-hyperplastics 23.3 per cent. are toxic and 76.7 per cent. are atoxic.

While the association of the constitutional symptoms with non-hyperplastic goiter involves to a certain extent a personal equation, this is to a very limited degree true for the cases having hyperplastic thyroids. The estimation that 23. 3 per cent. of the non-hyperplastic goiters are toxic is made on a very conservative basis.

Patients coming under observation with non-hyperplastic-toxic goiter give a history of having first noted the goiter at the average age of 22 years, and the evidence of intoxication at the average age of 36.5 years. The corresponding ages for hyperplastic goiter are, respectively, 32 and 32.9 years.

That non-hyperplastic goiter is noted ten years earlier in life than hyperplastic goiter, that fourteen and one-half years elapse between the appearance of non-hyper-

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

plastic goiter and the development of notable toxic symptoms, and that the constitutional symptoms were noted but a few months (between ten and eleven) later than the goiter in the patients affected with hyperplastic thyroid is alone sufficient to show that we are dealing with at least two distinct pathologic and clinical groups. That one is not the sequence of the other is self-evident.

Are all hyperplastic goiters coming to operation toxic? Throughout our series the number of cases in which the clinician failed definitely to note and attribute constitutional symptoms to the thyroid and which were later diagnosed hyperplastic goiter by the pathologists vary from two cases in 1909 to four cases in 1912. Two of these latter four cases were in children under 4 years of age and can be excluded in considering the hyperplasia of adults. The third case was that of a girl 15 years of age who gave a history of having noticed the goiter, periods of tremor, tachycardia and palpitation for nine months. These symptoms, however, were not attributed to the thyroid previous to operation. The fourth case was that of a woman 47 years of age who gave a history of having noticed the goiter for twelve years, rapid growth during the few months previous to coming to operation and a long train of symptoms, part of which might be attributed to thyroid intoxication. I have excluded a few cases that had small areas of hyperplasia in the thyroid because they are still under discussion by the pathologists. The majority of them had moderate toxic symptoms indicating that the activity of the thyroid is proportionate to the degree of the hyperplasia.

Is hyperplasia of the thyroid more prevalent in the first two decades of life than we have definite knowledge of, perhaps indicating a thyroid activity in response to some demand that cannot be considered far from normal? If so, is this hyperplasia of the thyroid to be sharply distinguished from the hyperplasia associated with exophthalmic goiter which develops at the average age of 32? I do not think that we can definitely answer these questions at present, though there is much evidence suggesting an affirmative answer, at least to the clinical side of the question.

Is the exophthalmos of thyrotoxicosis always associated with hyperplastic goiter? The pathologic reports fail to show the presence of hyperplasia in the cases in which exophthalmos was noted by the clinician, six times in 1909, four times in 1910, twice in 1911, and not in a single instance in 1912. Nine hundred and eleven new cases of goiter came to operation in 1912. In most of the exceptions to the rule previous to 1912, we have been able definitely to prove that there was an error in noting the presence of exophthalmos.

Should all toxic-hyperplastic goiters be included under the term "exophthalmic goiter"? Possibly there is a small group of cases which should not. That there is very little chance for error, however, in answering this question in the affirmative if we include only those cases coming to operation is indicated by the following facts: (1) Of the cases having diffuse hyperplasia of the thyroid coming to observation from one to three, three to six, six to nine, nine to twelve, twelve to eighteen, eighteen to twenty-four months, and over two years from the onset of toxic symptoms 50, 59, 67, 75, 80, 80, and 87 per cent., respectively, had exophthalmos (questionable cases excluded); (2) if we select from any period in our series twenty-five consecutive patients having hyperplastic thyroids and very mild toxic symptoms, over 50 per cent. had exophthalmos and if we select from the total number of patients coming to operation during 1911 and 1912 the twenty-five patients with non-hyperplastic thyroids having the most intense intoxication, exophthalmos is not noted in a single instance. It is quite possible that exophthalmos may be associated with non-hyperplastic-toxic goiter, but, if so, it is so rare that it must be in a way considered accidental.

Is the symptom-complex accompanying hyperplastic goiter to be directly attributed to disturbed thyroid function? While I have so considered it in this paper only as a matter of convenience for pointing out the association of the clinical and pathologic findings, and do not wish to get into a discussion of this subject at present, I do wish to call attention to a point in support of this theory that, so far as I know, has not hitherto been made, namely, that a person 22 years of age with an adenoma of the thyroid has a definite chance of developing a train of symptoms during the thirty-sixth year so similar to the symptom-complex associated with hyperplastic thyroid that the best-trained diagnosticians are constantly confusing the two conditions.

Can we associate the symptom-complex of non-hyperplastic-toxic goiter with any definite pathologic change in the thyroid? For the present I shall have to answer this question in the negative.

Correlating the statistical data herein given, we may safely come to the conclusion that exophthalmic goiter is a definite clinical complex always associated with hyperplasia of the thyroid and that it should be sharply distinguished from the constitutional state or states that may develop with non-hyperplastic goiter.

RECIPROCAL RELATIONS OF THE CLINIC AND THE LABORATORY IN MEDICINE *

T. W. HASTINGS, M.D.
Professor of Clinical Pathology, Cornell University Medical College, and Assistant Visiting Physician to Bellevue Hospital
NEW YORK

The clinic has been under obligations to the laboratory since the time of the first post-mortem descriptions of normal organs, and of pathologic changes in organs and tissues. Yet to-day one would pass over the founding of modern medicine by Rokitansky, Cohnheim and Virchow on pathologic and histologic anatomy, to the consideration of the more striking relations of the clinic to bacteriology, parasitology, physiology, physiologic chemistry, experimental therapy and laboratory diagnosis. It is not that pathologic changes in tissues are unimportant, but in the newer fields of research there has been so rapid a development of methods applicable clinically to the accurate diagnosis and to specific therapy and prophylaxis of infective and parasitic diseases, and the correction and regulation of toxic and antitoxic metabolic disorders of a non-invasive nature, that the earlier pathologic investigations must be considered of a former era.

The laboratory has forgotten that the original stimulus for its efforts came from careful observers of clinical conditions. Without this it is doubtful whether the laboratory worker would have shown the patience of his clinical contemporaries, and it is likely that he would have taken himself in despair to other fields.

As a matter of fact, within a few years the clinic has swung far afield from the onward course of scientific medicine in the attempt to avoid the overwhelming strides of experiment and of laboratory application and

---

from the practice of the results of experiment and observation which are beyond the ken of the unaided eye and hand. It is interesting to note that the first scientific aid to the clinician was through the methods of Auenbruegger, Corvisart and Laennec, assisting the ear.

No one would decry the value of anamnesis, physical diagnosis and experiential and statistical knowledge, any more than deny the complementary relation of the laboratory to such methods; but in certain instances, if not in many, as in diphtheria and epidemic diplococcus meningitis, statistical knowledge has made it evident that the laboratory has displaced the clinic in importance in the complementary relation. This is the fact which most clinicians, the rank and file of practitioners, deny—that there are diseases in which laboratory knowledge counts for everything, and that experience of thirty years develops less proficiency along certain lines than the modern first-grade medical school imparts to its latest graduates.

INDEBTEDNESS OF THE MODERN MEDICAL CLINIC TO THE MEDICAL SCIENCES

To the fundamental sciences of physics and chemistry, medicine is indebted more indirectly than directly, except in the case of physiologic chemistry, which has developed as a branch of chemistry essentially medical in application.

The chemical methods directly employed are of a simple nature and yet the chemical investigations which have enabled an understanding of normal and diseased processes have involved elaborate procedures on the part of highly trained experts. This lack of applicability of advanced complicated methods is due to the fact that chemistry, *per se*, has to do in part with inorganic substances which have so far as known little to do with processes of disease and healing. The chemistry of organic substances which play a considerable part in normal functions and pathologic states has been specialized in as physiologic chemistry.

Apart from the manufacture of anilin dyes, nonphysiologic chemistry has more to do with the synthetic processes for the preparation of drugs than with the workings of a clinic.

From physics many methods have been selected. The stethoscope, the sphygmograph and sphygmomanometer, the various forms of cardiograph, instruments for hemometry, the spectroscope, the polariscope, the calorimeter, the Roentgen rays and radium emanations, to say nothing of the numerous principles of physics applied to instruments for the diagnosis and treatment of diseases of special parts and for mechanotherapeutics and electrotherapeutics, are well known. The most widely used are the stethoscope, the sphygmograph, the Roentgen rays, the hemometric apparatus and the polariscope. There was a day not long since when apparatus for electrotherapeutics was more widely used than far saner methods of therapy, but fortunately this day is passing.

The application of certain principles of physics and the use of physical apparatus play a large part in modern chemical laboratory technic, but are subordinate as a rule to methods of physiologic chemistry, biology, pathology and bacteriology. While for a time such methods were absorbed by the clinic, at present along certain lines, as in roentgenography, the clinic must employ an expert technician and an interpreter of roentgenograms. The progressive clinic must employ an assistant especially trained in this particular branch of physics.

To physiology, as to anatomy and general pathology, medicine in every branch owes not only its allegiance, but also its existence, for without these three fundamental sciences inefficient empiricism would have prevailed, and no modern medicine would exist. It is true to-day that, with the exception of the application of the sphygmograph and the cardiograph and the simpler tests in neurology, the methods of physiology are less applicable to the clinic than to experimental investigation. The highly developed apparatus for such methods must be used by one of special training in physiology.

From physiologic chemistry many methods, both simple and complicated, have been drawn, on account of their applicability, as essential to the clinic for the daily routine for diagnosis. Some of the methods, as the testing of urine for albumin, sugar, indican, bile and blood, are available for any well-trained, proper-spirited physician, and for the fledgling hospital interns who through their laboratory training mainly have proved a worthy asset to the clinic. Many of the methods, however, are too complicated and too time-exacting for utilization without the assistance of properly trained graduates in medicine who have a liking for thorough study and investigation of cases.

This is no reason for not developing the facilities for conducting such work in connection with the clinic, and is an excellent reason for attaching to a medical clinic a trained laboratory assistant. In a well-conducted clinic, for example, the estimation of urea should be made in conjunction with the estimation of the total nitrogen and ammonia and other nitrogen-containing substances in the urine. The estimation rather than the determination of the presence of acetone bodies in the urine should be made by one qualified to do such work. For more advanced examinations for the investigation of problems in physiologic chemistry in relation to medicine the physiologic chemist must be not only consulted but also persuaded to become interested.

In experimental physiology, the elucidation of the nature and the treatment of certain thyroid diseases, and the understanding of circulatory and cardiac disease, stand out prominently among the achievements of modern medicine, as the results of infinite labor and patience of master minds persevering in the face of difficulties and discouragements.

The keen observations of certain contemporaries are comparable to those of Beaumont, Bernard, Gull and Addison. Since the prevalence of the diseases explained by these observations is relatively small compared to those investigated through pathology, bacteriology and allied sciences, it is from the latter that the most beneficent results have come. To pathology and experimental pathology one must credit the understanding of the nature and progress of disease and therefore the significance of a diagnosis and the rational employment of therapeutic measures directed particularly against the alleviation of symptoms, and the eradication of causative agents. Under the influence of pathology have developed bacteriology and parasitology, which have elucidated the etiology of so many diseases, the nature of which pathology had previously determined.

As important as the discovery of the etiologic agents of infection and parasitic diseases, has been the evolution of epidemiology, resulting in the elaboration of the methods for controlling epidemics of yellow fever, malaria, ankylostomiasis, trypanosomiasis, plague and the gradual reduction of the prevalence of typhoid fever. The discovery of "carriers" and the existence of such individuals dangerous to a community, while not well recognized by the practitioner and even doubted by some, should be impressed on medical students as realities to be sought for under certain conditions and properly cared for. Recently attempts have been made in a few instances to determine the number of "carriers" among convalescent typhoid patients in hospitals and so regulate their relations with surroundings that they will not become a menace to the community. From experimental pathology and experimental medicine have come the effective methods of treatment for rabies, diphtheria, tetanus, epidemic meningitis and the prophylaxis against variola. Whether from the clinician, the pathologist or the bacteriologist, such so-called brilliant discoveries have been the result of long painstaking, scientific investigation by minds of the same type, utilizing laboratory methods. The clinician may be a keen observer and may recognize remarkable shades of difference in the symptom-complex of diseases, but the one who explains the meaning and causation of the symptom-complex must be the scientific investigator, exemplified by the leaders in medical science. Most recent are the brilliant results of scientific investigation in experimental therapeutics, and one hopes to see studies in chemotherapy and in scientific investigation in materia medica place drug therapy on a sounder and more wholesome basis.

From the simpler methods of examination evolved through research in the medical sciences has developed the clinical laboratory employing methods available for clinical diagnosis, and necessitating the training of men in cytology and bacteriology and microscopy.

The fact that clinical laboratory assistants may learn readily the simpler chemical and physical methods for diagnosis but that it requires years of application to become familiar with and expert in clinical bacteriology, cytology and the microscopy of parasitic disease is not sufficiently recognized to-day.

THE INFLUENCE OF THE LABORATORY ON MODERN MEDICAL EDUCATION

Experimental investigation in physiology, physiologic chemistry, pathology, bacteriology and therapy have founded the conception, knowledge and treatment of disease on a firm scientific basis and have made necessary the use of laboratory methods for diagnosis and therapy. Without experiment there would be little of science and accuracy in the practice of medicine.

The most striking change in medical curriculums due to the modern conception of disease is the displacement of the didactic lecture and the theatrical clinic by demonstrative teaching and the clinical clerk or assistantship system in hospital wards and dispensary. The student no longer learns the symptoms of disease by memory, and therapeutics by rote, but is made to see, feel, investigate and think before drawing a conclusion. The consultant of thirty years ago lectured to his students and conducted a private clinical laboratory with one or two assistants, and followed with interest the necropsies in his cases, and to-day he teaches his students as assistants in hospital wards and dispensaries, and organizes clinical laboratories with capable assistants to whom he may send the students for a period sufficient to become familiar with the laboratory methods suitable for diagnosis. Students were thus formerly taught to diagnosticate through quizzing the patient and clinical observation, often superficial and perfunctory, since their minds were not stimulated to careful, minute observation by the habit of exactness, inculcated by familiarity with laboratory methods.

To-day a student is taught to diagnosticate through anamnesis, clinical observation, physical diagnosis, physiologic methods, methods detecting structural alteration and disturbance of function in organs primarily involved and in other organs and systems secondarily disturbed and through searching for etiologic factors producing a general disturbance before function is altered in an organ or before a system is attacked. Particularly important is the instruction given in prophylaxis and the prevention of the spread of infectious diseases. Experimental medicine and clinical laboratory methods have revolutionized diagnosis and to a great extent, though not so completely, therapy. The latter retains many of its deplorable features, not so much from faulty teaching as from the extended advertising and commercialism of drug-manufacturing firms, who by individual canvassing, as well as by advertisement and distribution of pamphlets, attract the attention of the young physician as he settles down in an office to await the growth of a practice.

Away from medical centers and university surroundings, the country practitioner should be more vulnerable to the advertised therapeutics than the city physician; but this does not always follow, since the tenor of present medical education leaves a habit of rejecting what is fundamentally wrong in practice. A deplorable attitude of the visiting physician and the practicing physician is that of indifference to necropsies, both in endeavoring to obtain them and in checking up the clinical observations when the post-mortem examination is conducted by competent pathologists. The figures given by Cabot for the coincidence of anatomic diagnosis at necropsy with clinical diagnosis should impress any one with the necessity for arousing interest in post-mortem examinations. Fifteen years ago the pathologists and a few progressive clinicians in this country had stirred some of the profession to activity, but of recent years, notably during the past five years, the clinician's interest in gross pathology has diminished alarmingly. The complacency with which most clinical diagnoses are made, the self-satisfaction with which the therapy is conducted on this diagnosis as a basis, are evidences of a faith unbounded, which should be replaced by careful and repeated observations to ascertain the facts before final judgment gives forth a diagnosis.

The figures quoted by Oertel, as those by Cabot, demonstrate how erroneous conclusions may be in medical practice even when based on the most painstaking clinical investigation assisted by careful laboratory tests.

This lack of interest in necropsies and this self-assurance in respect to clinical diagnoses have infested the hospital interns, excepting in a few institutions. It would be the better part of wisdom to insist that the hospital intern, if having through instinct and ambition no interest in necropsies, should be trained to appreciate their value, as the student is trained, and even made to perform, under the supervision of the pathologist, certain necropsies in cases from his wards.

The student in the best schools is trained to appreciate the knowledge gained through necropsies, but as a hospital intern, under the influence of experienced clinicians, his appreciation wanes and is often replaced by indifference to post-mortem examinations as to many other laboratory methods and other conceptions of disease taught previously by the laboratory departments.

Few clinicians are capable of performing necropsies, and it would not be desirable for them to undertake to perform them to any extent, for them the pathologist the most efficient reports are obtained; but the former, much to the satisfaction of the latter, might give evidence of a sincere interest in post-mortem reports.

The clinical clerk or assistantship system is a development *pari passu* with the laboratory and demonstration method of teaching. The lack of a sufficient budget as a rule limits clinical laboratory development in most teaching institutions, and the lack of realization of its importance limits it in hospitals, health resorts, and in private practice. Clinical laboratories will not be generally used until the present generation of laboratory-trained students replaces the passing generation of practitioners.

PRACTICAL DEVELOPMENT OF THE CLINICAL LABORATORY

For the Various Clinics of the Dispensary and Hospital.—Under the preceding paragraphs laboratory methods applicable to the clinic have been mentioned.

The best system of utilizing such methods is under dispute, judging from the organization of laboratory facilities in different medical schools and hospitals. Whether each clinical department shall develop within itself laboratory facilities which it needs or thinks it needs, according to its director, or whether a single clinical laboratory department to care for the needs, particularly along advanced lines, of the different clinics, shall be established, may depend on many factors. In the first-grade institutions for teaching and practice there is no doubt but that the latter method is preferable, as a system. The former method generally results in the assignment of the laboratory work to recently graduated assistants, who retain their positions, even as directors, for two or three years, so that the position is one of a rotating hospital intern or medical school assistant, which necessarily implies lack of familiarity with more advanced methods, and therefore lack of efficiency in teaching. And, strange to say, this system still prevails in medical schools which first introduced the laboratory assistantship to the medical clinic in this country. This is not so on the Continent. It is wise to relieve the student of much of the advanced routine and to concentrate his attention on some new or advanced method as an object of research.

Many advanced laboratory methods applicable to the diagnosis of conditions other than those of the medical clinic should be made available, through a central clinical laboratory, for other departments of the school and hospital. In some hospitals the interns are pathologic assistants during the first six months of service. The fault in this system is that after the sixth month the intern may do little or no laboratory work, if so inclined and not interested; and since laboratory examinations are made for him, as for his visiting physician, he forms the habit of having his work done for him, and later on in practice of neglecting to have it done. Six months' training is not sufficient to form the habit of doing such work as may be done by the practitioner.

In other hospitals, and the number is few, a clinical laboratory well conducted by the director of the pathologic laboratory or by a clinical pathologist is maintained, which results in the work being done on a high plane and in stimulating students and interns to interest themselves in laboratory study of cases throughout their service and thereafter in practice. This is by far the best system.

Again, in a few hospitals, the clinical laboratory work is conducted by young assistants attached to the medical and other clinics, and under their supervision by the interns; and while this method stimulates the interns and habituates them to the value of such work in practice, it maintains the laboratory service on a lower plane, since the recently graduated assistants, as directors of the laboratory and not under the supervision of a pathologist or clinical pathologist, do not reach the proper degree of efficiency in advanced methods during their short term of service.

The development of a clinical laboratory is, as a rule, considerably more advanced for medical than for surgical work and other clinics in hospitals. That this need not be so, and that a surgical clinic may benefit vastly by utilization of well-developed laboratory facilities, is evidenced by the superb organization at Rochester, Minn.

For Health Resorts of a Special and a General Nature.—Laboratories established at health resorts, in this country particularly, are for routine efficiency as part of a money-making venture, and, therefore, even when well conducted in their beginning by able men, become obsolete in methods and fall below the standard through lack of facilities for conducting thorough experimental studies, and the absence of the stimulating atmosphere of a university medical school or of experimental institutes.

The directors of health-resort laboratories might keep in touch with, and even be proficient in methods if they had the habit of visiting ocasionally university medical schools for courses of study; but as it is to-day, such visits are for a few fleeting days to clear up a theory, or obtain superficial acquaintance with some one procedure demanded by their clientele. There is no reason why such resorts should not take cognizance of the complications which afflict so many of their patrons, as well as of the disease with a name for which they ply their therapeutics, and occasionally search for the causative factors in diseases with which they become familiar clinically. Many instances will come to mind of worthy examples to follow.

For the Physician in Private Practice.—Within a few years there has developed in certain cities what may be termed a cooperative investigation association for diagnosis, the details of which may be obtained in Richmond, and in many smaller towns throughout the state of New York, and probably in many other states. Through a cordial cooperative system the laboratory knowledge of the recent recruits to the ranks of practitioners is made available to the mutual advantage of patients and the profession.

The influence of proper laboratory teaching is such that the student looks on disease from a different point of view from that of one who lacks such training. This point of view is that of always searching for the etiologic diagnosis, regardless of the name of the disease, and for the possibility of applying specific therapy, and results in the careful study of each case by all methods available. There is no question that the ultimate product, previously trained with such a point of view, is the more thorough diagnostician, and therefore one more capable of right practice, and this will be borne out by the next few generations of physicians who in practice will modify the present attitude of the average practitioner.

The length of time required for laboratory training is probably longer than for clinical training, to bring one to the same degree of proficiency in each, and it must not be forgotten that during the laboratory training the student and instructor are in close touch with the clinical aspect of each case. The specialist is such through his familiarity with the clinical and laboratory methods of diagnosis and therapy; and the new generations of family physicians will come into their own again on account of their ability to apply laboratory methods to practice, provided the medical schools live up to their possibilities.

ADVANCEMENT OF LABORATORY-TRAINED MEN TO CLINICAL POSITIONS

If one recalls the progress of clinical medicine during the past thirty years, one will appreciate that the most renowned and advanced clinics are those which have attached to themselves competent laboratory assistants and have been in close touch, amounting to cooperation, with the laboratories of the medical sciences or institutes of science allied to the medical sciences, and whose directors are men well trained in laboratories, as in Baltimore and Munich.

As feared by some there is danger in giving clinical positions to men who have done purely experimental work and little of it with one or two experimental successes, and to men long trained in one medical science. A man of such training with no clinical experience must of necessity submit to clinical training before efficiency for holding a clinical position is obtained, even as the clinician who has not previously had the requisite laboratory training, which is considerably more than there is time for in a medical school curriculum, is unfitted to direct a progressive medical clinic.

One cannot agree with many of the recent statements of Bevan.[1] Laboratory-trained men are not against the clinician, but would have the clinician made after a new pattern, thoroughly learned in laboratory methods through three or four years' experience while a clinical assistant, so that he may understand and interpret properly the utilization of physiologic, pathologic, bacteriologic and biochemical methods for diagnosis and for therapy.

Professors in medical sciences should be men who know considerably more of the subject they teach than the clinically trained men in medical schools ever hope to know on account of the little time the active clinical man can give to keeping apace with any medical science. The latter are not suitable for medical sciences, since the facts in detail, the truth entire, should be known by one, in order to teach the sciences, and it is impossible, with the tremendous development in the past twenty years, to be trained to teach in the medical sciences, unless one is a specialist, and often a specialist in one branch of a medical science.

Inspection of Water-Supply.—Let me for a moment note the fact that we have a most thorough inspection of the milk-supply, of our meat-supply, of food adulterations, but in how many communities in this country have we properly protected not only the inhabitants, but the stranger and traveler from infection by preventing the drinking of contaminated water from pumps and wells? You ask the average farmer or average person what he thinks about the water in the well on his premises and he will invariably tell you that the water is pure, clear and sparkling; and yet how many of these wells may not be contaminated with pathogenic germs? The inspection of many other things is no reason why a most thorough inspection should not be made of the wells, lakes, rivers and streams that all water supply not only in the cities but in the farming districts should be guarded. The state or county should order a most thorough control, and a periodical examination should be made and an official notice posted at all sources of water supply, stating the condition of the water, whether it is pure or otherwise, whether it is liable to bring about a disturbance of the gastro-intestinal tract or not.—Francis E. Fronczak, in *American Journal of Public Health.*

EPILEPSY AND PARESIS IN RAILWAY ENGINEERS AND FIREMEN *

CARL D. CAMP, M.D.
ANN ARBOR, MICH.

Although on several previous occasions medical men have called attention to the fact that epileptics and paretics are among those employed in connection with the running of trains and motor-cars and to the obvious dangers incident thereto, the subject has not apparently been given much consideration by the transportation companies, at least, so far as I have been able to ascertain by questioning the medical men they employ.

My attention was attracted to the subject through seeing three cases of epilepsy and two of paresis in the course of two years in men who were employed either as enginemen or firemen on locomotives.

While this is not a large proportion of the total number of cases of epilepsy and paresis seen by me, the points to be made are that these men were engaged in an occupation that made the disease a distinct menace to the safety of the traveling public as well as to their own, and that something could and should be done to prevent their employment in such occupations.

An abstract of the histories of these cases is as follows:

Case 1.—A. T., a railway fireman, aged 28, came to the hospital Sept. 28, 1912, because of having "bad spells." There was no history of nervous or mental diseases in the family. The patient was single, denied venereal disease, and showed no history of trauma. He did not use alcoholics, but smoked a considerable amount of tobacco.

May 27, 1912, he had the first attack of which he had any knowledge. He lost the power of speech, had a "faint" feeling through his stomach, his arms trembled, and finally he lost consciousness. He did not have incontinence, but bit his tongue in the attack and felt weak after it. About three weeks later he had another attack, similar except that he did not bite his tongue. About two weeks later he had still another attack. The attacks were all ushered in by the same aura and none of them occurred on the engine while at work. A neurologic examination was practically negative. The urine, blood and blood-pressure findings were negative and a physical examination was negative. The Wassermann reaction on the blood was positive. An examination of the fundi oculi and of the nose and throat was negative.

During his stay in the hospital he had an attack in which he first became apparently speechless, pointed to one of his companions and mumbled and then fell out of his chair. He bit his tongue and made a few convulsive movements. He was unconscious altogether about five minutes. Following the attacks he could answer questions, but was dazed. He returned to his position because he said that he was about to be promoted to be an engineer and did not wish to lose his place.

Case 2.—W. B., a railway fireman, aged 27, was admitted to the hospital July 8, 1911, complaining that at times he was irrational and had a headache. His family history was negative so far as could be learned from the patient. He had had only the ordinary diseases of childhood and denied venereal diseases.

The patient stated that the trouble came on in March, 1911, beginning with severe headaches which were accompanied by some visual disturbances. At times he had attacks of epileptic automatism; for instance, he arose at night and ran out of the house, running for almost a mile. At other times he had convulsive seizures. All the attacks occurred in the evening or at night. The neurologic and the physical examinations were negative. The examinations of the blood and urine and the Wassermann reaction were negative.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

The case was one of epileptiform attacks, possibly caused by beginning organic brain-disease. He did not intend to return to his work after leaving the hospital.

Case 3.—V. H. S., a railway fireman, aged 29, came to the hospital complaining of attacks of unconsciousness, April 9, 1911. The family history was negative and there was no history of epilepsy. He denied venereal diseases and used alcohol very moderately.

About nine years before his admission to the hospital he had a fall and, following the fall, a severe headache. About a month after this fall he suddenly became unconscious and remained unconscious for two weeks, after which he apparently recovered completely.

His trouble began eighteen months before his admission to the hospital with attacks of unconsciousness. In the first attack he was told that they tried to awaken him and could not. It came on while off duty, when he was asleep. The second attack occurred after a hard day's work. He went to sleep and when found was purple, with wide-open, staring eyes. On his admission to the hospital he was having attacks about every two months. They always came on while he was sleeping and he would soil the bed and occasionally bite his tongue. During the daytime he complained of attacks which he described as dizziness. He did not fall in these attacks, but they were actually attacks of momentary unconsciousness, in which he became slightly pale, had a staring expression and would not respond to questions. The neurologic and physical examinations of the patient were entirely negative.

RAILWAY MEN WITH PARESIS AT STATE HOSPITAL, KALAMAZOO, MICH., FROM JULY, 1910, TO FEBRUARY, 1913

Name	Occupation	Age	Date of Onset	Date of Admission	Remarks
B. C.	Engineer	45	October, 1908	October, 1911	
H. R. S.	Car inspector	37	January, 1907	May, 1912	
S. T.	Fireman	40	February, 1911	January, 1912	Would forget signals and had to be told to shovel coal.
C. F. T.	Engineer	55	June, 1909	July, 1911	
J. L.	Flagman	65	February, 1911	March, 1911	Had allowed a train to run into a street-car 2 weeks before admission.
W. V.	Railroad work	50	November, 1906	December, 1911	
F. M. C...........	Motorman	37	June, 1910	June, 1911	Discharged because of his queer talk.
S. G.	Engineer	31	June, 1911	October, 1911	
W. H. S.	Railroad clerk	52	December, 1905	December, 1910	In 1905 his car ran away from him and he was injured.
E. E. S.	Railroad clerk	53	....	....	Nothing of importance.
A. C. H.	Railroad brakeman	37	August, 1911	July, 1912	Nothing of importance in history.
C. L. B.	Engineer	40	November, 1910	October, 1911	Was discharged in October, 1911, after a wreck.
W. H. D.	Engineer	56	March, 1912	November, 1912	

The diagnosis was epilepsy of the grand mal and petit mal types.

Case 4.—B. K., an engineer, aged 56, came to the hospital June 10, 1911, complaining of nervousness and difficulty in vision with incontinence of urine. His family history was practically negative. The patient denied that he had ever had venereal diseases and said that he had never been ill before nor had he had any injury. He said that he was married and had eight children. He had been working at his occupation up to the time of coming to the hospital.

On examination he appeared very nervous and confused. There was a marked disorientation of time and space. He talked disconnectedly, and could give little or no information regarding his present illness, except that he had had more or less incontinence of urine for two years. He stated that he felt very well; "his only trouble was that his wife wanted him to take black pills and he wanted to take white." He obeyed commands but apparently did not fully comprehend what he was doing. There was a marked tremor of the hands when moving. His speech was typically paretic. His pupils were small, with no reaction to light, and the tendon reflexes of the lower extremities were not obtained.

The diagnosis was paresis, of at least two years' duration before his admission. His commitment to an asylum was advised.

Case 5.—P. B., railway engineer, aged 46, complained chiefly of numbness on the left side. His family history was negative. He had always been healthy. He did not use tobacco or alcohol and denied having had venereal disease.

His trouble began in February, 1909, when he had an attack in which he found that he could not use his left arm and could not talk. This attack lasted about ten hours, but he was not unconscious. In April, 1909, he had another attack, in which he did not lose his voice, however. The attack in this case was over in about fifteen minutes. From then until July he had similar attacks, sometimes as frequently as once a week, was never unconscious and never bit his tongue. In July he had an attack which affected the right side. On his admission to the hospital he had no special complaints but spent nearly all of his time in writing a very elaborate diary and many letters. He had an attack while in the hospital in which he lost his voice, he would not obey commands, and his arms and legs were rigid. He remained in this condition for about half an hour. He had no memory of occurrences during the attack.

The examination showed unequal pupils, with a sluggish reaction to light. The knee-jerks were exaggerated about equally on both sides, but otherwise the examination was negative. The examination of the spinal fluid gave a positive Wassermann reaction and showed an increased number of lymphocytes and an increased amount of albumin. He was overanxious while in the hospital to get back to work on the railroad; he said that the president of the road had written to him and that he wanted him back. He insisted that he felt as though he could work just as well as he ever could.

I am not alone in my experience in this connection. In 1908, Dr. P. C. Knapp[1] called attention to general paralysis as a menace to public safety in transportation, and a committee of the American Neurological Association reported[2], in 1910, on the number of paretics in asylums who had been employed by transportation companies. The committee practically confined its attention to paresis and gave the statistics for a number of hospitals and asylums, mostly in New York and Massachusetts.

Statistics furnished me from the State Hospital at Kalamazoo, Mich., and given in the accompanying table, show that there were eighty-seven patients with paresis admitted from July, 1910, to February, 1913, and of this number thirteen had been employed by railways in positions connected with the operating department; five were engineers.

[2] Tr. Am. Neurol. Assn., 1910, p. 238.

Whether or not the occupation has anything to do with the development of the disease I do not know. The constant nervous tension may have some influence in this respect, but the conclusion is certainly justified that there are men at work on railways in responsible operating positions who are epileptics or paretics.

If so much is true we may go on to consider what the result might be. In the report of an accident occurring in the past winter on one of the New York elevated lines, it is said:

> The accident, it has been charged, was due to the fact that the motorman in charge of the second train was not looking ahead, as he should have been doing. This, if true, affords an excellent illustration of the statement made by railroad officials that no matter how excellent may be the equipment of a train, or the mechanical and other devices installed for the purpose of safeguarding the line against accidents, unless the man directly on the job, be he engineer, motorman, conductor, flagman, signalman or brakeman, attends strictly to his duties and has his mind at all times on what he is doing, accidents are likely to happen.[3]

It may be objected that after an epileptic fit no man would be employed further in such a position and that the patient himself would wish to leave an occupation which his infirmity makes dangerous to himself and others. In respect to these points it can be said that frequently these patients do not know that they have epilepsy. They have attacks supposedly due to heat-stroke, indigestion, etc., or the attacks may be of the petit mal type with no consciousness of their existence on the part of the patient and no signs apparent to the casual observer. My own experience has convinced me that even when the patient does know the nature of his trouble, economic necessity may persuade him to take the chance and continue at his work.

In the case of paresis the patient usually has no true insight into his condition. He may complain of some of the symptoms—memory impairment, attacks, etc.—but he usually insists that he is quite capable in his work. The dangers in case an epileptic or a paretic is at the throttle of an engine, or in other situations that require an interpretation of signals and orders and constant vigilance, are too apparent to require extended comment. A certain number of accidents have surely been so caused; whether some of the serious accidents which were apparently caused by a deliberate disregard of signals or orders have been due to the same factor seems not at all unlikely.

There would be but little object in calling attention to this state of affairs if there were no way in which it might be remedied; but this, I feel sure, is not the case. I am reliably informed that all applicants for positions of this character are medically examined before they are accepted, and that for some of these positions repeated examinations of the vision are made. Different railways have somewhat different ways of carrying out these examinations, but no matter how these examinations are made the following points could be provided for:

Since we know that cases of epilepsy and paresis do exist among those to whom the running of trains is entrusted, and since the presence of these patients in an occupation of this kind is dangerous to them, to the railway companies and to the traveling public, it would be to the benefit of all concerned if the medical examinations included careful and frequently repeated inquiries into the presence of symptoms indicating the existence of these affections and, more important still, the use of objective tests, such as those of the pupillary reflexes, best calculated to demonstrate their presence and not requiring too much time in their performance. The selection of the tests to be employed and the value to be placed on each might be determined by an expert appointed by the company, who might then instruct the company's regular examiners either by printed instructions or by lectures, or better still by demonstrations in the use of these tests. A series of such tests might be given in a short time, and many of them simply noted in the course of other routine examinations. While such simple tests might not be absolutely diagnostic, they would have some advantages over the present method of diagnosis, that is, waiting for something to happen. If the suspicions of the company's regular examiner were aroused by his inquiries he could refer the man to a consultant who could make more extensive examinations.

924 Baldwin Avenue.

ABSTRACT OF DISCUSSION

Dr. C. Eugene Riggs, St. Paul: Some years ago I read a paper before the Mississippi Valley Medical Association on the subject of epilepsy as a menace, and I called attention at that time to the facts set forth by Dr. Camp. I also made reference to paresis, and recommended that, instead of having examination of engineers made simply by a physician or surgeon, there should be a competent neurologist to pass on all these employees whose condition is so vital to the welfare and work of a great railway system. My paper was called forth by a serious accident that happened in the East, evidently the result of a minor epilepsy on the part of the engineer.

Dr. C. B. Woodson, St. Joseph, Mo.: I have seen a number of paretics who were engineers and firemen on railroads. Some years ago a man who denied syphilitic history was running a passenger train on one of the most popular roads in our state, when he became violent and was overpowered by his fireman, who stopped the train. This man died a paretic in the state hospital. Another case that impressed me forcibly was that of a conductor on a freight train. He was brought to me by his family physician and I diagnosed the case as paresis, not, however, in an advanced form. The patient finally consented to go to a sanatorium, and he was observed sufficiently long to convince the family that he had paresis. While he was running on the train he had a fight or two with his brakeman, but the latter had superior strength and overpowered him. In reading of various accidents on railroads and of the persons responsible for them, it has occurred to me that possibly the greatest menace is the train-dispatcher. Recently there came under my observation a chief train dispatcher of an important system of railroad in the West, and I found that he had the jacksonian type of epilepsy. A serious wreck recently occurred near the capital of the state, and the train-dispatcher, who had been regarded as a very competent man, says that he was not well at the time. There is absolutely no reason why advanced paresis should not be recognized by any one who hears the patient talk or observes him closely, even excluding the Wassermann, but if the Wassermann is brought to our aid designing physicians and patients can not take issue with it. It would be cheaper and far better if the railway companies would give a little attention to this condition in their men. It would be an easy matter to have them placed in an institution for the purpose of observation.

I believe that if a body like this Section would set forth to the managers of railways the dangers incident to conditions of this kind not only as a menace to life, but also as needlessly subjecting them to suits for damages, they would look into the matter further, and some satisfactory method of examination of employees would be arranged for.

Dr. D. S. Booth, St. Louis: This to me is an important subject, as I have been connected with railways ever since

---

[3] New York Sun, Sunday, March 16, 1913

I have been in practice. I do not think that it is the custom of railway companies to employ knowingly any man who has either of these diseases; but the difficulty is to discover them. Murder and robbery are not permitted by law, but both are still going on. The only method we have of discovering these patients is when they come under observation. When the applicant seeks to enter service the examiner is not going to observe this condition, and the man will not tell him about it. Even after obtaining a history of venereal disease my greatest difficulty is to differentiate the diagnosis of these cases in order to prevent the men from going to work. Coming under the observation of the company's doctors is, I might say, tantamount to discharge. The men know these things and go to other doctors for treatment, and we see nothing of them until something happens perhaps that we have never seen in our service. I do not think that I have even known of an accident occurring as a result of these diseases. Recently a case has come under my observation which several years ago I diagnosed as epilepsy, but from the fact that it was the nocturnal form, and, further, that the patient was supported by outside influence, medical evidence perhaps and probably a brotherhood, and that he was on a switch-engine, he was permitted to retain his position. A few weeks ago he had an attack on his engine. If we do not have the support of the profession we certainly cannot prevent these things, and I, for my part, should be delighted to have any one give me an insight into how to detect these cases early, before the patients show any symptoms or serious accidents occur.

Dr. L. Harrison Mettler, Chicago: I do not think that there is any question but that it is expedient for railway companies to recognize as early as possible a case of disease on account of which life is exposed to danger. A friend told me that his father, an engineer on a run of only a few miles, but on a fast train, had figured out the number of things an engineer had to carry on his mind during that time, in order to be ready to meet emergencies. I expected him to say a large number, but was amazed when he told me that there were seven hundred different things to be borne in mind. The results of his investigation were published, I think in *Harper's Magazine*. He remarked that people seldom realize that when an engineer starts out on his run he must at once put his mind on parts of the engine, signals, orders, etc., and that in that short space of time this particular engineer had to carry absolutely in his mind and be prepared to meet about seven hundred emergencies. I raise this point simply to suggest that I have often wondered whether or not the strain has something to do with these conditions, in addition, of course, to actual disease, in some of these cases. Of course, diseased men, we know, ought not to be on an engine. But the strain has a tremendous import in these cases, and there is no question but that a long rest will help even non-diseased engineers.

Dr. W. Brown Ewing, Salt Lake: My experience with railway work has been that examinations are perfunctionary. The companies have a long list of questions regarding mumps, measles, vaccination, etc.; the applicant says yes or no; as he perhaps happens to have his legs crossed, one leg is tested; urinalysis is made—and that is about all there is to it. This condition has been largely forced on the companies by the men themselves. Some surgeons of railways are not allowed to strip a patient. They may turn down his shirt in front and examine his lungs with a stethoscope and his heart in the same way. A neurologic examination is never heard of so far as my experience goes. The patients whom I have had on the Denver and Rio Grande Railroad have worked for years without any suspicion of epilepsy, paresis, or any similar disease, until within a short time before they were referred to the neurologist. Another unfortunate feature is that a true epileptic is not always removed, be he telegraph operator, engineman, conductor or brakeman who acts also as a switchman, and it is not always possible to have these men removed. The labor unions have reached the point now at which they contribute 10 per cent. of the hospital fund and have 90 per cent. of the say as to what shall be done with it. That one feature will, it seems to me, force the companies to do away with collections from the employees entirely, and then treat only cases of injury or sickness in the line of duty.

Dr. Sanger Brown, Chicago: It seems to me that it is going to be a difficult matter for us to suggest anything that would be of particular value in carrying out the purposes which Dr. Camp evidently has in view, that is, the protection of the public. I do not believe that we can do anything of any particular use, as physicians, so far as epilepsy is concerned, because we know very well that there is no extended examination made between the seizures to enable us to say with any degree of positiveness that the patient is subject to epilepsy, unless the case has advanced so far that the surgeon can easily detect it. In many cases, however, we can determine with a great deal of certainty whether or not the patient has tabes or paresis.

This matter would not be materially helped by a rigid examination at the time the patient applied for employment. Usually he is a young man then and he would not have the symptoms of either tabes or paresis; after all, the main danger arises from the disease affecting those men who have been in the employ of the company for a number of years and who hold responsible positions. The serious disasters that have occurred have come about in this way: Some trusted employee was attacked with some of the episodes of these two diseases, giving rise to a disaster. We have all examined cases of aged men who occasionally come to us. I recall one case now. A man of about 45, who considered himself in good health, was about to cross a bridge when, as he expressed it, something gave way as though he might have been struck by lightning, shock came over him, he was blind for a few moments and had to be led into a drug-store where he was taken care of. An examination of that case probably a year before would have shown that that man had no knee-jerks and no pupillary reflexes. It is these sudden episodes that cause accident. I recall the case of an engineer who said that the light suddenly went out of one eye while he was running his engine, but fortunately the vision of the other continued until he could get to a place of safety. I cannot see how we could expect to do anything more practical than to recommend some method to protect the public against these episodes, and possibly the public might consider that any action along this line would interfere with public liberty. That is what we hear as soon as we invoke any arbitrary rule. If the employees in responsible positions were required to submit to a thorough examination, say every year or two, it seems to me this would greatly minimize these dangers. I do not think that much would be accomplished by an examination, no matter how rigid, if it were made only when the person applied for employment.

Dr. Leo M. Crafts, Minneapolis: This subject is of great importance. I hope that Dr. Camp's suggestion will be acted on favorably. I think that we should also include the word "taboparesis." I am reminded of a case that I had about twelve years ago, that of an engineer who had been on the road for several years and whose removal I advised because of tabes. He had marked symptoms, could not walk without a cane, had loss of reflexes, etc. I am not sure whether he had diplopia or not while I saw him. In trying to go through the living-room of his house he became lost and had to hunt around to get to the door. He was sent into the country for about a year's rest, and at the expiration of this time he came into my office and asked for a certificate to go back on the road. I refused to give it to him, stating that he had no business on the railway again. He was not persuaded, however. I heard nothing from him for three or four years, when he sent his compliments to me, and I found that he was back in the service running a switch-engine in the yards of a western city. He must have been taken back on the railway by virtue of his engineer's certificate, for it does not seem to me that any examiner would pass such a case.

Men occupying important positions in the service should be examined once a year, as Dr. Brown has suggested, and, referring to Dr. Ewing's remarks, we ought to urge the doing away with blank forms of examination. We should make out our own complete, independent report, regardless of any forms. A safety campaign is now being carried on over the country generally—a campaign that applies to the public, but I do not see that it applies much to the officials or others running corporations. If this safety campaign is needed, it should reach the officials of the railways and be taken up in the surgical associations of the different companies.

Dr. Lawrence B. Pilsbury, Lincoln, Neb.: Some time ago there was brought to the Nebraska Hospital for the insane a young man of about 30 who had been employed by a large railway system to operate a switch-tower at a junction in one of the smaller towns of the state. The management of this road is a careful one and few disasters occur, but this man had been working so recently that his last pay-check was sent to him after he had been committed to the hospital. This young man had evidently not attracted attention. The only obvious physical sign he showed was foot-drop caused by injury of the muscles of the foot in childhood, a defect which had never been repaired. The man was apparently and unquestionably a paretic, and that he should have been in charge personally of signals and switches, alone in the tower, was obviously preposterous.

Dr. Charles Gorst, Mendota, Wis.: No position connected with a railway is more important to the public than that of the man who runs a locomotive on a passenger train. I believe that a man's personal liberty should not be considered when he is incompetent to fill so important a place. My experience of nine years in the position I now hold, that of superintendent of the hospital for the insane, Mendota, Wis., emphasizes the fact that if proper investigations were made many men who are employed by the railway companies would be found to be incompetent long before the fact is ordinarily discovered. I do not know of any case in which such a man has been found to be *incompetent and discharged* by the railway company before he has committed some act for which the authorities have taken charge of him and committed him to an institution.

There is no question but that Dr. Brown's idea of frequent examination of employees by properly qualified men is the proper one. I see no reason why this Section should not do what it can for the protection of the public by passing a resolution favoring such examination. A man who was insane in our institution for years and was transferred as a chronic case to a county asylum was paroled by the superintendent of that institution to his brother and soon after was employed by the railway company and made flagman in the yards through which thousands of people passed on trains daily.

Dr. Charles W. Hitchcock, Detroit: A few years ago I saw a case of well-developed paresis in an engineer who later experienced a remission and so far recovered that he made a trial trip with another engineer; but becoming convinced that he would never be able to gratify his desire, he committed suicide.

Dr. George A. Moleen, Denver: I am reminded by Dr. Camp's paper of a case of specific thrombosis. About eight years ago a man presented himself with partial paralysis of one side of the body. In the course of the record it developed that he had been a fireman and was still in the employ of the railway company. He had frequently had lapses of consciousness prior to the onset of the weakness which he experienced, and he admitted that often he lost and resumed consciousness to find that the water level in the gage was considerably below the visible line. It occurred to me then to wonder whether or not some of the explosions that sometimes occur might not be due to lapses of this kind. From this it would seem that it is not only paresis, locomotor ataxia and epilepsy to which we should direct our attention, but also syphilis itself. I quite agree with Dr. Brown that examinations should be made at intervals, but the interval of two years is too long. If I recall correctly, the primary infection in this person was about eighteen months previous to the time of the manifestation of the symptoms. When we recall the lapses of consciousness and the possibilities of automatism and automatic acts on the part of men entrusted with the control of engines and having in their charge the lives of many individuals, we begin to shudder as we contemplate these conditions of mind. I think also we have all come in contact with the conditions in arteriosclerosis in which there are epileptiform seizures with a period of unconsciousness, and these acts are often committed by old and trusted employees.

Would it not also, then, be well to examine the condition of the arteries, as evidenced by blood-pressure, at stated intervals? I think that this is a serious question.

Dr. C. D. Camp, Ann Arbor, Mich.: In considering this entire subject we must also, of course, consider the point of view of the railway company, inasmuch as they do not wish to go to any prohibitive expense in making examinations such as the appointment of a competent neurologist might entail. Furthermore, the thing must be done in such a way that the men will not feel that they are continually being spied on.

In the case of one road, the consulting ophthalmologist has a clerk at each of the division points to make visual tests every six months; these clerks, of course, become rather expert. Then the head consultant has several assistants who go about, and whenever a case with any defect is reported to him, it is referred to one of these assistants.

The man who examines the visual acuity repeatedly could also examine the pupillary reflexes without very much additional time, and he could with an ophthalmoscope take a look at the eye-grounds without consuming much time. In the same way the man examining the employees, as they are examined frequently, or even the man who is examining the eye, could make it a practice to test the knee-jerks, without telling why he is doing it.

There could also be a simple suggestion to examiners that they should always inquire for dizziness, that they should ask to see the tongue and incidentally look for masses; in fact, *those little points* which after all have the highest diagnostic value, could be put in a series of instructions to examiners. I think it should be emphasized, too, that we are not making these examinations entirely for the benefit of the public. After all, the employee himself is very likely to suffer in a wreck; and the railway company is certainly going to suffer as the result of a wreck if it is obliged to pay damages. If we emphasize these two factors, the public will come in for protection at the same time.

FEDERAL CONTROL OVER THE MANUFACTURE OF SERUMS AND VACCINES *

JOHN F. ANDERSON, M.D.
Director Hygienic Laboratory, United States Public Health Service
WASHINGTON, D. C.

Under the authority of an Act of Congress, approved July 1, 1902, the Public Health Service maintains a supervision over the manufacture and interstate sale of viruses, serums, toxins and analogous products. In accordance with the provisions of this act, regulations have been promulgated in regard to the licensing, inspection and examination of the products, and also for the suspension or revocation of the licenses of those engaged in the production of biologic preparations for sale in interstate commerce or for importation into the United States.

While the law conveys very broad powers in respect to the supervision of manufacturers and their products and permits restriction of the interstate sale of evidently harmful articles of this kind, it does not give specific authority to refuse to issue a license for a product of unknown or doubtful therapeutic value. The possible abuses that may arise because of this omission are so many and varied that it would appear desirable that further legislation be secured, so as to provide for the proper labeling of all biologic preparations that are still in the experimental stage. Such a precaution on a label would tend to do away with the promiscuous use as therapeutic remedies of biologic preparations which are not thoroughly established, and would thus serve as a safeguard to physicians and their patients. Lacking authority to provide for the differentiation between products of established therapeutic value and those of an experimental nature, the Public Health Service has not been able to take satisfactory action in regard to many of the preparations now on the market which are frankly empirical and almost warrant the appellation of "shotgun remedies." Some of these preparations have either been put on the market by misguided manufacturers or are being marketed and even advertised, because of a supposed demand, with a full knowledge of their lack of scientific basis. Unless it can be shown by satisfactory tests that such preparations are directly harmful or are based on demonstrated false premises, their sale cannot be prevented under existing law, though they may have no therapeutic value and may even do harm to a patient because of his generally lowered resistance to toxic substances.

---

* Read in the Joint Meeting of the Section on Practice of Medicine with the Section on Pharmacology and Therapeutics of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

The justification for existing legislation is amply evidenced by the marked improvement that has taken place in biologic products and in the methods employed in their production. Since the law went into effect there has been a marked improvement in vaccine virus, so that "sore arms" are exceptional rather than the rule, as was formerly the case. On account of commendable competition in developing methods of purification, diphtheria antitoxin is of a higher potency, and serum reactions are now comparatively rare occurrences. Contaminated and weak serums have been detected and caused to be withdrawn from sale; a standard for tetanus antitoxin has been established, so that this important serum is now of a known and higher potency and definite dosage can be had; false and misleading labels have been to a large extent changed; and, in general, the manufacture of biologic products has been placed on a much higher basis as regards their purity, potency and methods of production. While the greatest good from the enforcement of the law has been to the physician and his patients, it has also been of great value to the careful and well-equipped manufacturer in forcing the less careful and poorly equipped producer to comply with the official requirements by improving his methods and facilities so as to insure uniformly safe and potent products.

In connection with the enforcement of this law a large amount of research work has been done in the Hygienic Laboratory. Other than the elaboration of standards of potency for diphtheria and tetanus antitoxins, I wish only to call attention to the work of the Public Health Service in furthering the use of antirabic virus for the prevention of rabies. Up to 1908 practically the only way in which a person could receive antirabic treatment was by going to some Pasteur institute, which frequently necessitated travel for a long distance. As a result of work done in the Hygienic Laboratory it has been shown that the virus may be prepared and shipped long distances and in this way the prophylactic has been made available for many who would not otherwise have received it. During the past five years antirabic virus for the treatment of over 4,000 persons has been sent from the Hygienic Laboratory to state boards of health and others entitled to receive it.

HOW SUPERVISION IS MAINTAINED

In accordance with the law and regulations framed thereunder, all persons or establishments engaged in the manufacture and interstate sale of viruses, serums, toxins, etc., are required to be licensed by the Secretary of the Treasury on the recommendation of the Surgeon-General of the Public Health Service after an inspection has been made of their establishments, methods and products. An inspector visits the establishment and examines carefully into the sanitary condition of the buildings and the condition of the animals, if animals are used for the production of the biologic product, and learns from those who have charge of the scientific work the technic employed; for instance, the methods of bleeding, collecting and storing the products and especially the methods used for safeguarding their purity and potency. He looks into the labeling of the products, paying especial attention to the date when they are labeled to be exchanged. Samples of the various products are also obtained and forwarded to the Hygienic Laboratory for examination.

Foreign establishments desiring to do business in the United States must submit to the same conditions and are required to have a license similar in all respects to that of domestic firms. The collectors of customs are empowered to detain at ports of entry biologic products pending examination in the Hygienic Laboratory as to their purity and potency and as to whether or not the products are correctly labeled as required by the law and regulations. Viruses, serums, toxins, etc., imported from foreign countries, are refused entry by collectors of customs unless prepared in an establishment holding a license or unless intended for experimental purposes.

The results of the examination of the samples obtained by the inspector and forwarded to the laboratory for examination and his report of the inspection form the basis of recommendations for or against the issuance of a license to that particular establishment. The inspector's report, together with the results from the laboratory, are considered by the sanitary board of the Public Health Service, which makes recommendations to the Surgeon-General as to whether a license shall or shall not be granted. In the event that a license is granted by the Secretary of the Treasury it is for a particular product and no general licenses are given for the manufacture of biologic products; but each vaccine, serum, toxin or similar product is considered separately.

After a firm has been licensed to engage in the manufacture and interstate sale of these products, samples are purchased on the market at frequent intervals in various parts of the country and forwarded to the Hygienic Laboratory, where they are examined, first, as to labeling; second, as to the potency of products for which standards have been adopted; third, as to sterility and freedom from toxic properties not inherent in the product itself; and, fourth, as to the amount of preservative. In certain instances they are also examined to determine their harmlessness to healthy individuals. If the samples are found to be deficient in any of the above named points, the matter is at once reported by the laboratory to the Surgeon-General of the Public Health Service, who, in the case of a lack of potency, contamination or excessive amount of preservative, may require the manufacturer to withdraw from the market all of that particular lot of serum that remains unsold. This is not a difficult thing to do, as manufacturers are required to label each lot with a laboratory number and to keep records as to whom the serum has been sold. When an infringement of the law or regulations has been discovered during inspection or by laboratory examination, the Surgeon-General recommends to the Secretary of the Treasury that the license of the offending establishment be suspended; and, if the conditions are not corrected within sixty days after suspension, he recommends that the license be revoked and the facts as to the cause of suspension and revocation of license may be published in a circular letter issued by the Secretary of the Treasury.

LICENSE NOT A GUARANTEE OF THERAPEUTIC VALUE

The fact that a firm is licensed to manufacture and sell in interstate trade a virus, serum or similar product does not mean that the government recognizes such a product as valuable for curative or prophylactic purposes. In fact, as pointed out above, under existing law the product may have little or no therapeutic value. Except for certain products for which standards have been established, such as diphtheria and tetanus antitoxins and the potency of vaccine virus, no potency requirements are enforced. In other words, the license to make and sell a product in interstate traffic does not carry a governmental guarantee of its therapeutic efficiency; it simply means that this product has been examined to see that it is truthfully labeled in that it contains the manufacturer's name, the license number and an exchange date, and that it is free from bacterial or toxic properties not inherent in the product itself. For example, some firms are licensed to sell normal horse-serum provided it is so labeled and is free from impurities; also, there are certain serums, such as antityphoid serum, antipneumonia serum and others of like doubtful efficacy, and still other serums or products in the experimental stage of development, which are sold under a license; but the license to sell these products does not mean that the government in any way endorses the present or prospective therapeutic value of the products. This brings up an important question in regard to this class of unknown or experimental preparations. There is no authority for a satisfactory control over these kinds of products at present, and efforts should be made to obtain legislation giving such authority and also giving additional facilities and money for a more strict laboratory supervision, so that we may at least know if they have an experimental basis for their use, or even if they are what they claim to be.

BENEFITS DERIVED

Some of the advantages so far secured in the control of these products by the Public Health Service may be summarized as follows:

1. All manufacturers have been required to put their stables, barns and laboratories in good sanitary condition and to keep them so.
2. When work with tetanus, tuberculosis, etc., is done in laboratories producing diphtheria antitoxin, a complete separation of such work is required.
3. All establishments are required to be equipped with proper laboratory facilities and personnel to insure the safe and efficient preparation of the several products for which a license has been granted.
4. Each lot of vaccine virus is required to be examined, bacteriologically, and a special test made for tetanus bacilli, and detailed records kept of such examinations.
5. The sale of the old style "dry" lymph points is no longer allowed.
6. All animals used for the propagation of vaccine virus are required to be necropsied and the virus from any animals proved to be suffering from a communicable disease other than vaccinia is not allowed to be sold.
7. All serums are now required, in addition to tests for potency, where standards are established, to be examined for and to be found free from bacterial and toxic contamination; to be correctly labeled; to state the date beyond which they cannot be expected to yield their specific effects, and to contain no excessive amount of preservative.
8. Standards for diphtheria and tetanus antitoxins having been established, physicians have a knowledge of the exact amount of the dose used in each instance.
9. A standard for tetanus antitoxin having been established, it is now possible to use known and comparable amounts of the particular make of serum, and thus valuable data may be gathered as to the amount of tetanus antitoxin needed for prophylactic and curative purposes.
10. When the physician uses a package of diphtheria or tetanus antitoxin he may feel assured that every known safeguard has been thrown about its production and that it contains at least the number of antitoxic units stated on the label.

ANTISTREPTOCOCCUS SERUM[*]

GEORGE H. WEAVER, M.D.
CHICAGO

In the protection of the animal body against virulent streptococci two factors are known to be of importance. The bacteria are first acted on by opsonin, which is found especially in the blood-serum, and thus prepared for phagocytosis by the leukocytes in which they are destroyed. The normal body usually possesses sufficient antistreptococcic power for its protection against streptococci as they occur on the mucous membranes, tonsils, etc. If the normal resistance is lowered, or an unusual number or highly virulent bacteria gain entrance to the body through some defect in the protective mechanism, the bacteria may multiply and produce disease. When such an infection runs a favorable course the streptococci stimulate the body cells to produce immune opsonin which in turn acts on the streptococci and prepares them for phagocytosis and destruction by the leukocytes. A coincident increase of leukocytes also heightens the power of the body to destroy the invading bacteria. While phagocytosis, following on efficient opsonification, explains the elimination of infecting streptococci, it does not, however, make plain the mechanism by which the toxic effects of the bacteria are overcome. We know but little of the essential composition and action of the so-called endotoxins of streptococci or of the ways in which they are neutralized in the body.

Since living streptococci during the course of an infection stimulate the production of immune opsonin, Nature may be assisted by injecting the bodies of streptococci which have been killed in various ways with the object of calling forth a similar result without the danger of a fatal infection. Dead bacteria have been found to act in a manner similar to the living and on this principle the vaccine treatment of streptococcus infections has been built. Immunity induced in the individual animal by viously employed in immunization work, that is, the preparation of a serum by the inoculation of a number of different races of pneumococci, hoping thus to prepare a polyvalent serum efficacious against practically all the races likely to be encountered. This has seemed to me a crude method of dealing with the problem and one not likely to advance our knowledge of the exact conditions concerned.

---

[*] Read in the symposium on Serums and Vaccines at the joint meeting of the Sections on Pharmacology and Practice of Medicine of the American Medical Association at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

[*] From the Memorial Institute for Infectious Diseases, Chicago.

Without going into the details of the methods which have been described elsewhere by Dochez, it may be stated that the pneumococci isolated from cases of pneumonia which I have studied may be divided into four groups. The organisms belonging to each of the first two groups are specific, so far as their immune reactions are concerned. An immune serum produced by the injection of a horse with a race belonging to Group 1 has a specific action against all the members of Group 1, but has no effect on the organisms of any of the other groups. In like manner, an immune serum produced by the injection of a horse with a pneumococcus belonging to Group 2 is protective against all the other members of this group, but has no effect against the members of any of the other groups. In Group 3 are included the organisms of the so-called *Pneumococcus mucosus* type. These organisms have very large capsules and produce a sticky exudate in animals. So far it has not been possible to produce an active immune serum against this variety, though an effective active immunity may be obtained. An immune serum produced by a member of any of the other groups has no protective power for any race of this group. In Group 4 are included all the races against which Serums 1 and 2 are not effective and which, from their other properties, do not belong in Group 3. Animals may readily be immunized to any member of this group, and the serum of the immunized animal is protective against the race used for immunization. In no instance, however, has this serum been found effective against any other race of this group or against the organisms of the other groups. So far as cultural and morphologic characters are concerned, no constant group differences have been discovered between the members of Groups 1, 2 and 4. By means of the agglutination reaction of the various races, however, it has been found possible to group them in exactly the same manner as by protection experiments.

It has become evident, therefore, that while a large majority of cases of pneumonia are due to pneumococcus, so far as immune reactions are concerned the cases of pneumococcus pneumonia are caused by organisms of at least four different types, and, from the point of view of specific therapy, this is equivalent to saying that they are due to at least four organisms. In seventy-four cases of pneumonia studied the number of cases found to be due to organisms belonging to each of four groups is shown in Table 1.

TABLE 1.—CLASSIFICATION OF SEVENTY-FOUR CASES OF PNEUMONIA

Type of Organism	Number of Cases	Percentage
1	35	47
2	13	18
3 (mucosus)	10	13
4 (heterogeneous)	16	22

It is now evident that in studying the effect of an immune serum on patients with pneumonia, but slight conclusions can be drawn from its indiscriminate employment in all cases. First, we must know the type of organism used for its production, and second, it must be employed only in cases due to organisms of this type. So far, it has been possible to produce a serum of high protective power against organisms of Type 1, and a second serum, only slightly less efficacious, against organisms of Type 2. As previously stated, it has been impossible to produce a serum active against organisms of Type 3. To produce a serum active against organisms of Type 4, it would be necessary to immunize an animal against every obtainable race of this group. This would not be practicable. So far as the treatment of pneumonia is concerned, however, this is of minor importance, since our observations indicate that pneumonia due to organisms of Type 4 is of relatively slight severity, and most of the patients recover without any specific treatment. This is shown in Table 2.

TABLE 2.—MORTALITY

Cases Due to	No. Patients	Died	Per Cent.
Type 1	34	8	24
Type 2	13	8	61
Type 3	10	6	60
Type 4	15	1	7
Total	72	23	32

At present, therefore, the problem has resolved itself into treating the cases of pneumonia due to organisms of Type 1 and Type 2 with Serum 1 and Serum 2. In order to treat the individual case, however, it is necessary to have a method of determining very promptly, after the patient comes under observation, the type of organism concerned. It has been found possible to do this by using the following method: When a patient with pneumonia is admitted to the hospital, a culture is immediately made from the blood and also one from a portion of sputum coughed up from the lung, or, when this is not obtainable, a culture is made directly from the lung by the insertion of a needle. This procedure seems to be without danger. When there are large numbers of virulent organisms in the sputum, a culture may be most rapidly obtained by injecting the sputum into the abdominal cavity of a mouse. After four or five hours the peritoneal cavity may be washed out with salt solution and the cells thrown down in the centrifuge; a suspension of the organisms is thus obtained. However the culture is obtained, the agglutination test is at once applied. If the organism fails to agglutinate with either Serum 1 or Serum 2, it is, of course, useless to undertake serum treatment. If, however, one of the serums agglutinates the organism, treatment may be commenced at once with the appropriate serum. Later the organisms have been studied by testing the protective power of the serum, and in all cases the protection test has corresponded with the agglutination test.

We have now shown certain reasons why the use of immune serum in the past has not been efficacious, and methods have been described whereby, theoretically at least, such serum may be rendered effective. It may be assumed that given serums of high protective power against organisms of Groups 1 and 2, the early determination of the nature of the infecting organism and the early administration of large doses of the appropriate serum should have a favorable influence on the course of the disease. So far it has been possible to test this assumption on only a comparatively small number of cases, since the work so far has been largely preliminary and done with a view to establishing the practical application of the serum on a sound experimental basis.

Serum has now been administered in twenty cases of pneumonia. In one of the first cases a further study of the organism showed it to be of Type 4, so the use of serum was discontinued. In two cases the patients were admitted in the last stages of the disease and the serum was administered only a few hours before the patients died. Seventeen cases have therefore been treated with the serum. Of these, fourteen were due to organisms of Type 1 and three to organisms of Type 2.

The method of administration of the serum was as follows: On admission, 2 c.c. of serum were injected subcutaneously to discover if the patient was hypersensitive. As soon as the type of organism was determined, from 50 to 100 c.c. of the serum, diluted one-half with salt solution, were injected intravenously. The condition of the patient served as a guide in the later treatment. Usually the serum was not administered oftener than every twelve hours. The patients treated received totals of from 190 to 460 c.c. of serum, except one, who received a total of 700 c.c. of serum. Treatment was commenced on the third day in six cases, the fourth day in four cases, the fifth day in three cases and the sixth day in four cases.

The patients treated were all seriously ill, the most severe cases we have had during the winter. In the fourteen cases due to Pneumococcus 1, all of the patients recovered but one, and in the three cases due to Type 2, one patient died. This patient, however, objected to the treatment and would not allow its continuation, so it was not thoroughly carried out. When we consider that the mortality among the cases due to Types 1 and 2 is very high, the result is certainly not discouraging. The number of cases is much too small, however, for any conclusions to be drawn from the results as regards mortality.

At present conclusions as to the efficacy of the serum must be based on other criteria. Let us first consider the effect on the clinical course of the disease. Temperature curves are not here presented, since erroneous conclusions may be drawn unless all the curves are presented, and in the present instance this is impossible. Following practically all the injections, a reaction has occurred. The temperature usually rises, and then falls, but does not necessarily remain low. In two instances the rise of temperature has been marked. In the other cases the rise of temperature following the injection was only a degree or so. In all the cases except the fatal ones, the serum has apparently had an ultimate favorable effect in lowering the temperature and shortening the course of the disease, though, of course, this is a very difficult matter of which to be absolutely sure. In no case was one injection of the serum sufficient to bring on a crisis. All the patients seemed to feel better following the injection of the serum, and in a number of cases the apparent lessening in the degree of intoxication was very manifest.

When the treatment was commenced early, no extension of the involvement of the lung occurred. On the other hand, however, there was no special tendency in the treated cases for the lung lesion to resolve rapidly. If anything, there seemed to be a tendency for resolution to be delayed in these cases. This has been noted by others in certain cases treated by serum. One of the patients developed a pneumothorax with empyema. Operation was performed and recovery ensued. Fortunately, this was not one of the patients in whom the lung was punctured for culture. Three patients later developed signs of fluid, and aspiration of small amounts of fluid was performed. The fluid in these cases was sterile and operation was not necessary.

More important than the foregoing criteria, however, in indicating an effect of the serum, are the following observations, since they have depended solely on objective procedures: First to be mentioned is the effect of the serum on the organisms in the blood. In eight cases pneumococci were isolated from the blood before the treatment was commenced. In all cases blood-cultures were made before each treatment, and in all of these cases after one treatment and before the second (or within from eight to twelve hours) the blood had become sterile. The conclusion seems justified, therefore, that one large dose of active serum given intravenously is sufficient to sterilize the blood. It also seems certain that if the organisms are not present in the blood, the administration of the serum will prevent their invasion.

Second, in a previous study of the protective substances in the blood-serum of patients with pneumonia,[3] it has been shown that, as a rule, the appearance of protective substances in the blood, when demonstrable, coincides rather sharply with the period of critical fall in temperature and the disappearance of symptoms. Before the crisis they are not present in the blood in any measurable degree.

A similar study has been made by Dochez of the protective substances in the serum in a number of the cases of pneumonia treated with serum. In all the cases studied, it has been possible to demonstrate the appearance of such substances in considerable amounts in the serum very shortly following the administration of one dose of the immune serum, even when this serum has been administered early in the disease, at a period when such protective substances are otherwise never present. These substances persist, and in case they play a part in the mechanism of recovery, as was concluded from the previous study, it is evident that their appearance indicates a favorable action of the immune serum.

The results obtained, therefore, from the clinical and laboratory study of this series of cases of pneumonia treated by the injection of large amounts of appropriate serum, seems to indicate that a method has been devised for the successful specific treatment of at least a portion of the cases of acute lobar pneumonia.

The mode of action of immune serum in these cases is still obscure. We have found no evidence of a bactericidal action of this serum, either *in vitro* or *in vivo*. The evidence that the effect is due, to any considerable degree, to the presence of bacteriotropic or opsonic substances is still inconclusive. The effect on the patients seems to indicate that the effect to some extent, at least, may be due to the presence of antitoxic substances. Until the toxin responsible for the symptoms in pneumonia is isolated, however, the final proof of antitoxic action cannot be demonstrated. It has been shown,[4] however, that when living pneumococci are dissolved in bile, the resulting solution, when injected into rabbits and guinea-pigs, is very toxic. By means of experiments on animals, which will be reported elsewhere, it has been possible to demonstrate that the toxic action of such an extract may be neutralized by the addition of proper amounts of the corresponding immune serum. Such extracts have also been found to be lytic for red blood-corpuscles, and it has been possible to inhibit this lytic effect by means of the corresponding immune serum. It is therefore evident that in case this toxin plays a rôle in the symptoms of this disease, the action of the serum in man may be due, in part at least, to its antitoxic properties.

SUMMARY

Antipneumococcus serum, in order to be effective, must be given early, in large amounts. Since pneumococci, so far as their immunologic properties are concerned, are divided into distinct groups, it is necessary in any case to administer the serum active against the group to which the organism infecting this case belongs. Highly active serums against two groups of pneumococci have been obtained, and treatment has been carried out in a small number of cases. The effect in these cases has been favorable and the mortality has been very low. In judging of the value of the serums, however, other facts are considered of more importance; namely, first, that bacteria in the blood are destroyed, and second, that immune substances, which ordinarily appear in the blood about the time of crisis, appear in the treated cases very soon after the administration of the serum. Lastly, there is some experimental evidence that part of the action of the immune serum may be antitoxic.

Sixty-Sixth Street and Avenue A.

PROGRESS IN ANTITYPHOID VACCINATION DURING 1912 *

FREDERICK F. RUSSELL, M.D.
Major, Medical Corps, U. S. Army
WASHINGTON, D. C.

Not until the close of the past year, 1912, has it been possible to know how much protection can be obtained from the use of antityphoid vaccine when administered to a large number of men of susceptible age. In the latter part of 1911 the use of antityphoid vaccine was made compulsory for all men in the service under 45 years of age, and as a result we now have records for the year 1912 covering approximately 85,000 vaccinated men. Of these 58,000 were stationed in the United States proper and the remainder in the colonies.

TABLE 1.—TYPHOID FEVER—UNITED STATES—ENLISTED AMERICAN TROOPS

Year	Mean Strength	Absolute Cases	No. of Deaths	To Each 1,000 Soldiers, of the Command, the Ratios Are For Cases	For Deaths
1901	26,515	250	17	9.43	.64
1902	39,736	341	34	8.58	.86
1903	42.264	246	12	5.82	.28
1904	43,940	247	12	5.62	.27
1905	42,834	153	13	3.57	.30
1906	40,621	230	12	5.66	.28
1907	35,132	124	7	3.53	.19
1908	46,316	136	11	2.94	.23
1909	57,124	173	16	3.03	.28
1910	55,680	129	9	2.32	.16
1911	55,240	44	6	0.80	.11
1912	58,119	15	2	0.26	.03

Table 1 shows the typhoid experience of troops in the United States for the past eleven years; the average strength of the home army, the number of cases and deaths are given, and also the morbidity and mortality per thousand of mean strength.

To elucidate this and the following tables the following data are furnished: Voluntary vaccination was begun in March, 1909, and 830 men were vaccinated during that year; too small a number—the strength of the army considered being 57,124—to influence the ratios. In 1910 a much larger number, 16,093, were immunized, and some effect on the morbidity and mortality rates became apparent, both being the lowest ever recorded in the medical history of the Army. In 1911, however, prophylactic immunization was even more generally used. Up to March it was entirely voluntary, but during that month was made compulsory for the Maneuver Division, about 20,000 men, assembled in Texas and along the Mexican border. In June the order was extended to all recruits, from 2,000 to 3,000 per month, since which time all recruits have been given the initial dose of typhoid vaccine as well as small-pox vaccination on the first day of service. The last and most important step was the extension of compulsory vaccination to all persons in the military service under 45 years of age, and this was made in the last quarter of 1911. The full effect of antityphoid vaccination was not, however, apparent until recently, when the statistics for 1912 were compiled.

TABLE 2.—TYPHOID, CASES, DEATHS, ETC.—OFFICERS AND MEN—UNITED STATES PROPER

Year	Total Cases	Total Deaths	Infected Prior to Enlistment	Among the Vaccinated No. of Cases	No. of Deaths
1909	170	16	?	1	0
1910	139	10	?	4	0
1911	44	6	?	7	0
1912	18	3	5	6	0

Table 2 covers only the period during which vaccine has been used, and differs from Table 1 in including officers with the enlisted men. It also shows the number, during 1912, who developed the fever before immunization could be carried out, patients undoubtedly infected before enlistment; in addition, the number of cases occurring each year among the vaccinated is stated.

TABLE 3.—TYPHOID, 1901-1912, FOR THE WHOLE ARMY, AT HOME AND ABROAD—OFFICERS AND ENLISTED MEN

		Cases		Deaths			Occurring Among Those Who Were Vaccinated	
Year	Mean Strength	Number of	Ratios per 1,000 of Mean Strength	Number of	Ratios per 1,000 of Mean Strength	Per Cent. of Total Cases	Cases	Deaths
1901	81,885	552	6.74	74	.88	13.0	..	..
1902	80,778	565	6.99	69	.85	12.2	..	..
1903	67,643	348	5.14	30	.44	8.6	..	..
1904	67,311	293	4.35	23	.33	7.8	..	..
1905	65,688	206	3.14	20	.30	9.7	..	..
1906	65,159	373	5.72	18	.27	4.8	..	..
1907	62,523	237	3.79	19	.30	8.0	..	..
1908	74,692	239	3.20	24	.31	10.0	..	..
1909	84,077	282	3.35	22	.26	7.8	1	0
1910	81,434	198	2.43	14	.17	7.1	7	0
1911	82,802	70	.85	8	.10	11.4	11	1
1912	88,478	27	.31	4	.044	14.8	8	0

The use of the typhoid prophylactic has not, however, been confined to the continental limits of the United States, but has been used also in Porto Rico, Panama, Alaska, Hawaii, the Philippines and China. Table 3 gives the typhoid experience for the entire army, at home and abroad, officers and enlisted men, for the past eleven years, the same period covered by Table 1.

It will be noticed that the lowest death-rate attained previously to the introduction of vaccination was 27 per hundred thousand in 1906, and the lowest morbidity was 320 per hundred thousand in 1908. From these two low points, the best ever attained under sanitary measures alone, the rates have fallen precipitously to 4.4 and 31 per hundred thousand, respectively. In 1912 the number of cases in the entire service was reduced to one-tenth and the number of deaths to one-sixth of the best record before vaccination, and for many reasons this radical reduction in our rates can be shown to be due to the typhoid prophylactic.

---

* Read in the Symposium on Serums and Vaccines at the joint meeting of the Sections on Pharmacology and Practice of Medicine of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

Charts 1 and 2 express graphically the morbidity and mortality rates given in Table 1, and the parallelism shows quite clearly that the improvement is not confined to cases only, but is equally evident in the number of deaths, about which there can be no doubt or question as to the diagnosis.

Chart 3 is a graphic chart of the non-effective rate for typhoid and paratyphoid for ten years. This ratio is a true measure of the amount of sickness in the Army from these two diseases; it shows the number of days lost per thousand men of average strength for the year, including both days spent in hospital and those spent in quarters or on leave of absence during the period of convalescence, and it shows very clearly the great gain in efficiency since the introduction of vaccination; the lowest non-effective rate previously to vaccination was ten times the rate for 1912. A study of this chart alone should carry conviction to any contractor or large employer of labor or to any one responsible for the health of many persons, such as educators and the superintendents of large institutions.

The question of correct diagnosis is one which merits consideration; it is conceivable that some mild cases of typhoid fever might masquerade under other names and, to a certain extent, vitiate the statistics. For this reason a study has been made of the rates for malaria and undetermined fevers in comparison with typhoid, and the study shows a diminution of all three; it is therefore clear that no appreciable number of cases of typhoid have masqueraded under these heads.

It is still too early to obtain complete records for any part of 1913, but reports for the first five months have been received from all posts in the United States and they are given in Table 4, in comparison with those of previous years. The last case of typhoid in the Army occurred Dec. 19, 1912, in an unvaccinated man.

The significance of a statistical table is not readily apparent without comparison with familiar facts, and for this reason Table 5, comparing typhoid death-rates in the army with those in civil life, has been prepared.

It is interesting to note that even before the introduction of vaccination there was less typhoid in the Army, as a rule, than among the civil population of the registration area. In eight of the past ten years the Army rate has been lower than the civil, and during the past three years, that is, since antityphoid vaccination has been used at all extensively, it has been very much lower; and this is true notwithstanding the considerable and progressive decrease in the civil rate, which, for 1911, was the lowest yet recorded by the Census Bureau.

In a recent issue of The Journal,[1] can be found the typhoid rates for the larger cities of the United States, and it will be seen that in only one (Cambridge, Mass.) was the 1912 rate lower (2.8) than for the Army. The thought readily suggests itself that extensive use of vaccine in civil life would bring about a corresponding improvement.

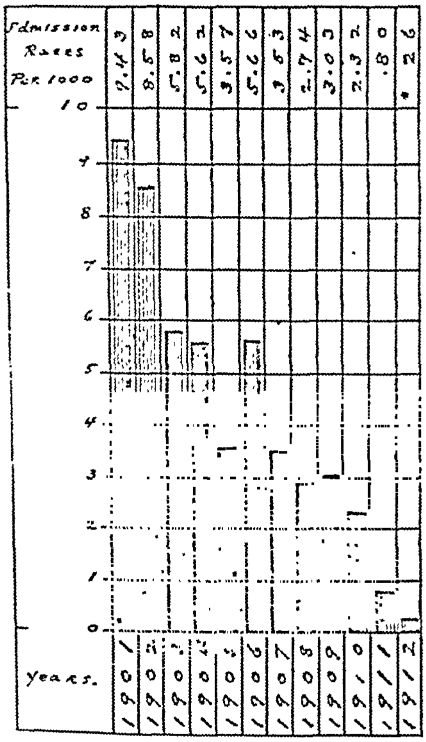

Chart 1.—Admission rates for typhoid. United States (enlisted men).

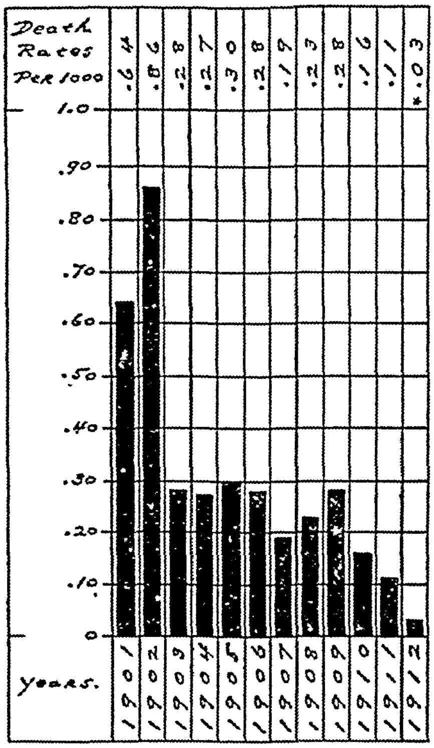

Chart 2.—Death-rates for typhoid. United States (enlisted men).

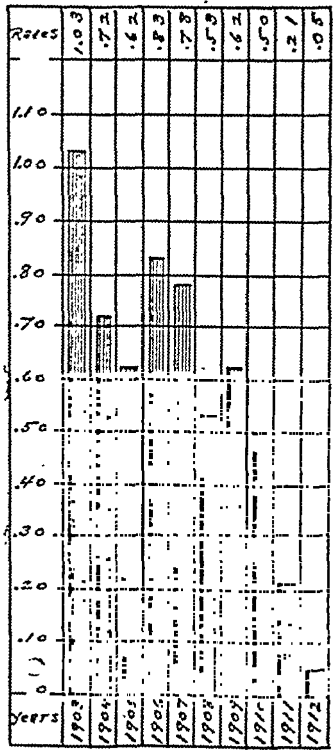

Chart 3.—Non-effective rates for typhoid for the Army—officers, American troops, Porto Ricans and Philippine scouts; includes paratyphoid.

The duration of the immunity obtained from the vaccine used in our service remains unknown. The idea that it lasted only so long as agglutinins or other antibodies were demonstrable in the blood-serum was, of course, untenable, since we know that following an attack of typhoid fever agglutinins cannot be detected for more than a few months, yet the immunity remains, as a rule, for life. Immunity after vaccination among English troops in India[2] does not appear to last over thirty months, but for various reasons we expect, and are obtaining, a longer period of immunity. Definite deductions, however, cannot yet be made because of the comparatively small number of men inoculated during the first two years. Another obstacle is the occurrence of an unknown number of cases of paratyphoid fever, clinically indistinguishable from typhoid itself. We now know that such cases cannot be correctly diagnosed by agglutination reactions alone, since these are frequently misleading, but that blood-cultures are necessary. Until paratyphoids are correctly diagnosed and excluded from the tables, it will be impossible to know the exact limit of immunity. It, no doubt, diminishes gradually, as after vaccination against small-pox; and the practice has been adopted of revaccinating against both typhoid and small-pox at the beginning of each four-year period of enlistment in the Army. This is done, not because there is good evidence that the immunity has all disappeared, but for the reason that it does not seem wise at present to trust to anything less than the maximum immunity obtainable.

---

[1] Typhoid in the Large Cities of the United States, special article, The Journal A. M. A., May 31, 1913, p. 1702.

[2] Firth: Jour. Roy. Army Med. Corps, 1911, xvi, 589.

The Army is as well protected against small-pox as repeated vaccination can make it, and for this reason it is interesting to compare the results obtained by vaccination against these two diseases. During the past four years vaccination against small-pox has failed in conferring absolute protection against infection in fifty-three instances, one of which was fatal; during the same period, although among a smaller number of men, antityphoid vaccination has failed only twenty-seven times, with one fatality from hemorrhage. The absolute numbers are given in Table 6.

TABLE 4.—TYPHOID CASES—UNITED STATES—OFFICERS AND ELISTED MEN—U. S. ARMY*

Years	Jan.	Feb.	March	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Total First 7 Months
1908	5	6	4	2	3	11	14	31	25	26	12	8	45
1909	4	10	6	4	11	15	26	14	16	45	20	6	76
1910	8	11	1	4	2	6	12	27	21	16	20	11	44
1911	3	3	3	7	4	4	4	7	4	4	1	0	28
1912	1	2	2	0	0	3	1	4	1	4	0	1	9
1913	0	0	0	0	0	..	..	..	..	..	..	..	0

*Paratyphoid fever included in figures for 1908, but excluded in other years. Cases of paratyphoid: 1909, 3; 1910, 3; 1911, 2; 1912, 3; 1913 to date, 0.

The immediate results of vaccination have been described in former articles and will not be referred to further. During the past four years over 200,000 persons, mostly in the military or naval services, have been immunized without any fatalities or untoward results. There have been no reports of cases indicating that the vaccination has activated latent tuberculosis or any other disease; in fact, as regards tuberculosis, there has actually been a diminution in the number of cases of all classes of tuberculosis during this period.

TABLE 5.—DEATH-RATES PER ONE HUNDRED THOUSAND POPULATION

Year	Army United States Proper	Registration Area U. S. Census
1903	28.0	34.1
1904	27.0	31.7
1905	30.0	27.8
1906	23.0	31.3
1907	19.0	29.5
1908	22.0	24.3
1909	28.0	21.1
1910	16.0	23.5
1911	11.0	21.0
1912	3.0	?

We make it a rule to vaccinate the healthy only, and any febrile illness, whatever its nature, automatically postpones vaccination. It is perhaps to this precaution that we owe our freedom from bad results.

The practice of antityphoid vaccination has been a pronounced success in the military and naval services, in hospitals, schools, institutions and in the camps of pleasure-seekers and contractors; in fact, wherever in military and civil life it has been used. We feel that its more general use, especially among the young, is advisable. The fact that it occasionally fails to confer complete protection is not a valid objection to its use, but rather an indication for its repetition at intervals to be determined in the future. A practical program is easily formulated on the following basis: No prophylactic vaccination is needed by persons living in a city or country district in which the typhoid rate is continuously low. If, however, a person, young or adult, leaves such a region for one in which the typhoid rate is high or the chances of exposure greater than at home, vaccination is indicated. It is, of course, indicated in cities or country districts with high typhoid morbidity. Revaccinations may be managed after the pain used in vaccination against small-pox, that is, in childhood, youth, and again when exposure threatens.

TABLE 6.—COMPARISON OF SMALL-POX AND TYPHOID VACCINATION—ENTIRE ARMY—OFFICERS AND ENLISTED MEN

	Small-pox			Typhoid		
Year	Number Vaccinated	Cases	Deaths	Number Vaccinated	Cases	Deaths
1909	74,692	7	0	830	1	0
1910	81,434	17	1	16,093	7	0
1911	82,802	20	0	30,000?	11	1
1912	88,478	9	0	88,478	8	0
Totals		53	1	......	27	1

It will certainly be as efficacious in civil life as in the Army, and its more general use will hasten the time when typhoid fever will become a negligible factor in our public-health problems.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. ANDERSON, COLE, WEAVER AND RUSSELL

Dr. Joseph L. Miller, Chicago: In the study of the various phases of disease there is none which probably offers so many difficulties as the study of the value of therapeutic measures; and in the study of the value of therapeutic measures there is no class of diseases so difficult as the acute infections, because they are largely diseases which have a self-limited course and in which there is a large percentage of spontaneous recoveries and a great variance in different epidemics, as well as in the intensity of the infection in individual cases. It, therefore, becomes necessary that the person undertaking the study of any therapeutic agent shall have had either a wide experience in the study of the diseases in which he has kept careful individual data, or else a suitable number of control cases. In a study of this character it is well for us to draw a sharp line of distinction between medical impressions and medical facts. The papers to which we have listened to-day are of especial interest and value because they deal with facts, not with medical impressions.

Dr. Walter V. Brem, Los Angeles: Advantage ought to be taken of this time to speak of those doubtful laboratory products the exploitation of which has so confused the minds of many of the men in the profession recently and against which the government is at present unable to protect us.

The first of these is Phylacogen, or Schaefer's Vaccines. Some time ago I attended a meeting in southern California at which Dr. Schaefer read a paper. He stated that he had treated a case of tuberculous meningitis with tubercle Phylacogen. He thought that the evidence that this case was tuberculous meningitis was complete because he had a spinal fluid in which the mononuclear cells were increased and in which the acid-fast bacilli were found. He said also that the Nonné test for globulin was absent. In the discussion I asked him if animals had been inoculated; he said they had not. He was much surprised that I would not accept the case, without animal inoculation, as a case of tuberculous meningitis. He reported that the patient had reached a normal temperature, with relaxation of the muscles of the neck and disappearance of other symptoms by the end of three days, after three injections of Phylacogen, and that six weeks after treatment had been begun the man was attending to his business regularly.

In the further discussion I pointed out that we had not been given reports from men whom we knew as to the action of Phylacogen. I said that we should have had such reports before the Phylacogens were put on the market. I was told that Parke, Davis & Co. had put Phylacogens in the hands of seven hundred physicians, and that the reports from these physicians were obtainable or were available for inspection, in the files of the house. I replied that we did not want to go to a commercial house for our scientific data; that, so far as I could find, Dr. Schaefer himself had published only one report on the subject of Phylacogens, and that was in a journal said to be controlled by the commercial house selling the Phylacogens. I was able to find only two or three other reports in our medical literature, and these were of insufficient character, by men whom we did not know. I said that we wanted reports from authoritative sources in our own profession, from men whose observations we knew we could trust and who had no commercial axe to grind; men who have at heart the good of humanity.

It does seem to me now, however, that the immense sale of these Phylacogens and the number of people being experimented on demands that they be investigated by men equipped to carry out the investigations in a thorough way.

Dr. W. W. Tompkins, Charleston, W. Va.: I have seen three cases of rabies in the past twelve months, one in a man 69 years of age, another in a boy of 9 and a third in a girl of 5 years. I should like to ask one question in this connection: If a man who was bitten by a dog was presented for treatment, and the symptoms of rabies had developed, should he be informed that there is no authority for treating him, moreover that it would be ineffectual to give him any treatment?

About one-fourth of our population is colored, and these colored people, relatively speaking, are bitten much more frequently than are the white people, for they have more pet dogs than the white people have. I have never known one of these colored people to die of hydrophobia or rabies. Furthermore, in the cases that I have observed, those persons who were lacerated and badly torn have not developed the disease, and generally those who were just bitten slightly did develop it.

Every now and then we see or hear of cases of typhoid carriers like that of Typhoid Mary; I should like to ask Major Russell whether or not a carrier if injected with typhoid virus would cease to be able to communicate the disease.

Dr. H. S. Munro, Omaha: Nine-tenths of every patient's psychophysical potentialities are dormant and are utilized or available only when called into action by the influence of environmental stimuli. The nervous system not only acts, but it also reacts. It is the reaction that counts when a man is sick, and by suggestion we can heighten the resistive powers of the cells comprising the totality of the organism and augment the recovery of pneumonia patients. My success in the treatment of pneumonia has been in every way comparable with Major Russell's success with vaccine immunization for the prevention of typhoid. Nine of my twenty-two years in medicine were spent in general practice, and I had but a single death from pneumonia in patients above 2 years of age. This death occurred in a man of 68, who, following typhoid, had a pneumonia complicated by an enormous pleuritic effusion. I wish that other physicians would try out this method in the treatment of pneumonia and make a comparison of the results with those of vaccine treatment.

Dr. W. E. Scott, Adel, Iowa: I should like to ask Major Russell whether the tincture of iodin that is used in sterilizing the skin is freshly prepared, or whether something is added to it to prevent the changes due to age. It is known that destructive effects on the skin sometimes result from the use of old tincture of iodin, but I do not know how soon this change takes place.

Dr. Henry Hansen, Jacksonville, Fla.: I should like to ask Dr. Cole how he determines whether or not a patient will react with anaphylactic shock, how much serum is injected in order to determine that and also what time he has given for the symptoms to appear.

Dr. L. A. Knopf, New York: I should like to ask Dr. Russell if he has any suggestion to make as to how he can stop certain enterprises which claim to cure tuberculosis by atoxic living bacilli.

Dr. Van G. Yaeger, Hayward, Wis.: I should like to ask Major Russell why there is not more agitation for muzzling dogs to prevent rabies.

Dr. D. A. Herron, Comfrey, Minn.: I have read that one Dr. Allen, a former associate of Wright of London, recommends strongly the use of a standard vaccine, that is, a simple vaccine of pneumococci, in lobar pneumonia. Has Dr. Cole any opinion on the use of simple vaccines of pneumococci?

Dr. Rufus I. Cole, New York: We have made no extended test of the medical treatment outlined by Dr. Munro.

In order to determine whether or not the patient is sensitive to serum, we have, in every case, immediately on admission to the hospital, injected 2 c.c. of horse-serum and then continued our treatment as soon as we could determine the nature of the organism concerned. Possibly 2 c.c. is too large a dose. It may be thought better to use a much smaller amount. I know of diphtheria patients who have shown marked symptoms following the injection of 2 c.c. of serum. This will be a problem to be taken up later when we give the method of treatment wider application.

I have had no experience with the vaccine treatment of pneumonia.

Major Frederick F. Russell, Washington, D. C.: We have been unable to cure carriers with any vaccine which we have made. In regard to the treatment of typhoid patients by vaccine, we have had, for reasons which are evident, little material. Men I know have used typhoid vaccine in the treatment of cases, and some of them are quite optimistic; others are not. I myself have had almost no experience; what little I have had has been encouraging. The iodin used on the skin is the ordinary 7 per cent. tincture of iodin. Some use a 50 per cent. solution; others full strength; it is simply painted on the skin. We have never felt that prophylactic vaccination in the first stage of typhoid has done the typhoid patient any harm. We vaccinate a great many children; the dose is determined by weighing the child. The dose for an adult is based on an average of 150 pounds; if a child weighs 50 pounds, we give it a third; if the fraction does not come out conveniently, we increase rather than diminish the dose. Children do not react so strongly as adults; in fact, it seems to be a rule that the younger the person, the less the reaction.

Syphilis, "G.P.I.," and Tabes.—Another curious fact in favor of the syphilitic origin of tabes is, as was shown by Krafft-Ebing, that general paralytics are insusceptible to inoculation with the syphilitic virus. I do not know if the same has been proved in respect to tabes, but probably the result would be the same.—George Pernet, in *Clin. Jour.*, vol. 35, p. 374.

CHRONIC ARTHRITIS *

LEONARD W. ELY, M.D.
DENVER

In announcing a series of articles on diseases of bones and joints the editor of one of our medical journals said recently that they would set forth "certain surgical methods quite different from those generally accepted." Therein he was in error, as no "generally accepted" surgical methods exist. The treatment seems largely a matter of temperament and environment. Especially is this true of chronic joint disease, and it will remain true so long as we depend for our inspiration on clinical experience. Clinical experience always has failed us in advancing our knowledge, and it will fail us here. We have still much to learn, but we are picking our way slowly through the tangle. At present chronic arthritis falls to a great extent in the domain of the orthopedic surgeon, but the deeper I go into the subject, the more I am convinced that chronic arthritis must finally be handled by the internist. Some of the reasons for my belief will appear from what follows.

What I set forth is based on the laboratory study of about 120 specimens, as well as on clinical study.

CLASSIFICATION

All cases of chronic arthritis can be divided into two great classes or types. The second type includes such lesions as Heberden's *nodes and morbus coxae senilis*, and, on account of lack of time, will not be discussed here. The other type includes by *far the greater number* of all cases of chronic joint disease. Its chief characteristic is a proliferative inflammation of the synovial membrane or of the lymphoid marrow or of both.[1] Depending entirely on the intensity and extent of this inflammation the bone and cartilage atrophy and disappear.

Mark well that the changes in the bone and cartilage are simply the result of the changes in the marrow and synovia.[2] There is nothing active about them.

PATHOLOGY

The changes in the synovia can be observed more easily than can those in the marrow. If the membrane be irritated, mechanically or otherwise, it undergoes a thickening and a villous proliferation. Its reaction is much the same, no matter what the nature of the irritant. Thus, if an inflamed joint be opened, the picture that presents is the same, whether the cause of the inflammation be syphilis, gonorrhea, typhoid, repeated mechanical injuries or a hemorrhage. Indeed, the gross changes wrought by tuberculosis are also the same, and we can only make the differentiation by demonstrating the tubercle. Further, the same morbid changes appear in the progressive multiarticular form of arthritis—the so-called "rheumatoid" arthritis,[3] Goldthwait's atrophic and infectious arthritis,[4] Nathan's metabolic arthritis,[5] Nichols and Richardson's proliferative form,[6] etc.

Let us turn now to the lymphoid marrow in the bone-ends. The characteristic change in the type under discussion is a chronic proliferative inflammation, which eats away the bone and cartilage, and, if severe enough, destroys the nutrition of both. The morbid process can reach the joint in one of two ways, by perforating the articular cartilage, or by entering the joint at its margin. The disease may exist indefinitely in the marrow, and possibly may never invade the joint cavity at all. In such case cultures from the joint would be negative.

The skiagram in all such cases, no matter what their cause, would show the same results, namely, a thinning and erosion of the cartilage, or its disappearance, and a rarefaction of the bone, possibly its partial destruction.

Pathologic identity implies identity of symptoms and of physical signs. In spite of all the clinical work that has been done on these joints, the various diseases which compose this type of arthritis cannot be differentiated from one another by their joint manifestations. If the patient were covered with a sheet, exposing the affected joint only, and if a history were denied us, we could not make a diagnosis as to the causal disease, even if an excellent skiagram were furnished for our inspection. In other words, as long as there is no sinus formation, the clinical picture may be the same in syphilitic, gonorrheal, typhoid, tuberculous, traumatic and hemorrhagic arthritis, and of that multiarticular progressive form which has passed hitherto under so many different names.

We have therefore, at least in the gross manifestations, pathologic identity, and identity of symptoms and of physical signs. How then can we make the diagnosis? Unless we can demonstrate the offending organism, only by considering circumstances outside the joint, and by weighing probabilities.

ETIOLOGY

We know that recurring trauma can produce the changes described, or some of them, and that the gonococcus, the *Spirochaeta pallida*, the tubercle bacillus and certain other germs can do the same. There remains that great group whose cause has never been absolutely demonstrated, although various observers have recovered pure cultures of cocci from the inflamed joints, and some have produced the disease by injection of these cultures into animals.[7] Shall we regard this group as "metabolic," or shall we believe that, after the manner of every non-traumatic chronic joint disease whose cause we have discovered, these cases also are due to micro-organisms?[8] Clinical evidence supports laboratory findings. Those who have searched diligently for a possible source of infection have often found it, and, removing it, have cured the patient.[9]

With clinical and pathologic evidence to support us then, we may adopt the working hypothesis that every non-traumatic chronic arthritis, like every non-traumatic acute arthritis, is due to an infection of the lymphoid marrow or of the synovia, or both.

SYMPTOMATOLOGY

The symptomatology of this type is comparatively simple in its essentials. The joint is usually swollen, and more or less painful and limited in its motion. Muscular atrophy may or may not be present. The joint may contain fluid or it may be a mass of fibrous adhesions. Constitutional symptoms, fever, etc., may be present or absent. Secondary infection may occur with any member of the group except the peculiar "cryptogenic form." A marked uniarticular nature is characteristic of some; a multiarticular of others. Certain others are sometimes uniarticular, sometimes multiarticular. There is no one symptom or group of symptoms peculiar to any member of the group, nothing that can be used to distinguish it from its fellows. The only way of making a positive diagnosis is by the demonstration of the causal organism or, in the case of tuberculosis, of the tubercle.

---

TREATMENT

If our hypothesis is correct, that every non-traumatic case in this type is infectious in its nature, the main indication for treatment is manifestly to find the focus of infection if we can, and to remove it. Local treatment occupies an entirely subordinate position except in tuberculosis. In tuberculosis local treatment is practically all we have to offer, always with the addition of general constitutional measures.

Chronic syphilitic arthritis, contrary to the teaching of most text-books, is by no means rare. Sometimes, when we are absolutely unable to find any definite source of infection, a course of anti-syphilitic treatment is advisable, on general principles. In my hands the iodids have proved of less service than mercury and salvarsan. Strangely enough immobilization seems absolutely useless in a syphilitic joint.

For a chronic gonorrheal arthritis the main indication is to set the genito-urinary tract in order. Until this be done all local treatment is simply palliative.

The progressive, multiarticular form has presented until recently a practically unsolvable problem, but the outlook now is by no means hopeless. He who writes off a prescription on the spur of the moment, or tries the latest panacea for joint diseases will continue to bemoan his results. Everyone of these cases furnishes a field for patient study, and the more thorough the study is, the more frequently a focus of infection will be found in some other lymphoid tissue of the body—a diseased tonsil, appendix, lymph-follicle or lymph-node. A suppurating tooth socket, nasal sinus or ear may be responsible, or a chronic intestinal infection, according to some authorities. In the last case we are on somewhat uncertain ground. Syphilis is almost certainly responsible for some cases. The tonsils should be removed as a routine measure, even when nothing points to their disease.

SUMMARY

The points which I wish to emphasize are: All the members of one great type of the chronic arthritides have a common symptomatology and practically a common pathology. With the exception of the traumatic cases, those whose nature is known are infectious in their origin. Those whose exact nature is still unknown are almost certainly infectious in their origin also. The treatment usually consists in removing the infection.

520 Metropolitan Building.

ABSTRACT OF DISCUSSION

Dr. Richard C. Cabot, Boston: I want to ask Dr. Ely whether he has seen cures in any of these multiarticular cases of unknown origin by the removal of the focus of infection. We have for years been told to find these foci of infection, and many of us have tried to find them; often we do find them, but I have yet to see any cases improved.

Dr. Van G. Yeager, Hayward, Wis.: Dr. Ely recommended the removal of tonsils whether they were diseased or not. It has been said that rheumatic infections especially enter the body by way of the tonsils, but it has not been proved. Probably the tonsils filter out rheumatic organisms. If we remove the tonsils we simply remove the filter.

Dr. Joseph L. Miller, Chicago: Dr. Ely is touching directly on the etiology of these cases when he takes the stand that focal infections are responsible for practically all of these chronic joint infections. I believe that time will show that he is correct. I certainly have seen cases of chronic joint infections where the trouble has disappeared just as much as one could expect it to disappear from a joint in which there were more or less permanent anatomic changes. The stand he takes in regard to the appearance of the tonsil is of importance. A tonsil may appear to be perfectly normal; the patient may state that he has not had an attack of tonsillitis since childhood; still, when such a tonsil is enucleated, there may be found at its base an abscess, and cultures made from that abscess will show the presence of hemolytic streptococci. An injection of these cultures into rabbits will produce chronic arthritis. It has been my experience with many of those patients that after the removal of the tonsil the joint trouble disappears.

Dr. Collins Johnson, Grand Rapids, Mich.: May I ask Dr. Miller to tell us in what way the use of Phylacogen helped some of these chronic cases? A woman from Grand Rapids, after being treated unsuccessfully by a number of men in Grand Rapids, finally consulted Dr. Miller. She told me that he administered Phylacogen and sent her home well. I wish Dr. Miller would explain that.

Dr. Joseph L. Miller, Chicago: This lady to whom the doctor refers had an attack of tonsillitis in November. I saw her in June. She had had the tonsils enucleated immediately after that. She had arthritis in one hip; it continued. She had been treated by somebody at Johns Hopkins with vaccines. She was no better. She came to me with this story. I may say right here that when the Phylacogens were introduced, Dr. Schaefer used them in the County Hospital in a large number of acute infections, and I have seen results from Phylacogen in acute articular rheumatism which, I believe, have not deceived me. I am not advocating the way in which the Phylacogens have been promoted, nor am I supporting them at this time. I stated to this lady that she had had everything done for her rheumatism that I knew of, except the taking of Phylacogen, and that if she wanted to take them, I was willing to administer them to her. She said she was willing to take anything to get well. She took the Phylacogens, and as far as I know, she is well.

Dr. L. W. Ely, Denver: I have seen these joints cured by removing the source of infection. Do not understand me as saying that the tonsil is responsible for these joint infections in every case. There is no panacea for joint infections—no one organ that is responsible for all cases. One must examine the patient from head to foot, and then must try to decide on the guilty organ. In the present state of our knowledge it is a case of weighing *probabilities*. If one guesses the tonsil, one will strike it more often than in any other organ. I cannot answer the question as to how one knows that a tonsil is diseased; it is impossible to tell until the tonsil is removed; in fact, even then one cannot always tell.

I cannot speak about the filter action of the tonsil, because we know very little about that. We do not know what the function of the tonsil is as yet. But I do know, and I have proved it in my practice to a limited extent, that when the lymphoid tissue in the joint is *infected, the infection* usually comes from some other lymphoid tissue in the body. The work is based primarily on pathology, and clinical results confirm laboratory findings. You cannot cure your *patients' joint* absolutely, even when you take out the focus of infection, *if the joint tissues are destroyed*. If the cartilage is gone, the joint will never be movable *again* without an *operation*; but as to checking the disease, and, in the early cases, curing it by the removal of the infection, I know that it can be done, for I have done it.

HEMORRHAGE FROM THE NON-PREGNANT UTERUS *

JOHN B. DEAVER, M.D.
PHILADELPHIA

Even a casual glance over recent literature indicates that the subject of uterine hemorrhage is so complex as to make practically impossible a comprehensive classification of causes. At the same time, the subject is simple enough to be readily understood. Such confusion indicates ignorance of the underlying principles of menstruation—its anomalies and abnormalities. Without accurate knowledge of the regular menstrual function, attempts to treat departures from the normal must depend almost entirely on empiric rules, the result of experience in practice. Such clinical experience, in the treatment of the various forms of uterine hemorrhage, I may claim without unduly violating the canons of modesty. It is on the result of this experience that I wish to speak.

In practice one meets hemorrhage from the nonpregnant uterus during the three important epochs of a woman's life—puberty, the child-bearing period and the menopause. Whatever the time of life at which such bleeding occurs, it may be said to depend on either local or constitutional causes.

Under constitutional causes we may at present include those little understood forms of hemorrhage supposedly due to interference with or departure from the normal in the internal secretion or secretions of the ovary and other ductless glands. Such abnormality may be presumably in the quality, quantity or regularity of the secretion, but the bearing on treatment has not yet been determined.

Other better understood causes are chronic visceral diseases (heart, lung, liver and kidney), infectious fevers, syphilis, general arterial sclerosis with high blood-pressure, leukemia, hemophilia and essential anemias, including chlorosis.

In any given case of uterine hemorrhage without easily demonstrable local cause, these various factors should be ruled out before one resorts to the ubiquitous and overworked curet. Curettage in these cases is of no permanent value, although it may lessen temporarily the menorrhagia and metrorrhagia. Such improvement is, however, always transitory. It may be interesting to mention that Whitehouse reports 20 per cent. of failures in a large number of patients submitted to curettage, indicating that one woman in five has been subjected to operation unnecessarily—a strong indication against the prevalent methods in diagnosis and treatment of uterine abnormalities.

Treatment in cases of menstrual anomalies of constitutional origin resolves itself into treatment of the underlying causes. Menorrhagia and metrorrhagia are only two of the many local indications of a general condition which requires the adoption of proper hygienic and therapeutic measures for its relief or cure. The local symptoms require local treatment in very few cases.

There are certain cases, however, without demonstrable local or constitutional causes, which, for want of a better term, are usually considered cases of endometritis. Curettage cures them and the scrapings show the well-known appearance of hyperplasia and hypertrophy of the endometrium and its glands. It is very probable that a certain number of these cases arise as the result of a mild superficial infection, and this is especially to be considered if the patient also has leukorrhea.

Every method of diagnosis should be exhausted, including bacteriologic examination of the uterine cavity, before a patient is relegated to the class of those suffering with "simple endometritis"; and, for reasons to be considered later, girls during adolescence are never included in this class.

Local causes of uterine hemorrhage include practically every form of disease which may occur in the pelvis; infections of the uterus from gonorrhea or after puerperal sepsis, myoma, polyp and cancer, tears of the cervix, retrodisplacements, tubal, broad ligament, tubo-ovarian and ovarian disease. In this connection it must be remembered that bilateral ovarian tumors, particularly carcinoma, frequently cause amenorrhea as a result of complete destruction of ovarian tissue. Constipation is included among the local causes for the reason that it produces uterine congestion by mechanical obstruction to free venous flow from the pelvis.

Whether both local and constitutional causes produce hemorrhage by setting up a so-called endometritis or by their action on the vasomotor or muscular mechanism of the uterus, I am unable to say. Such hypertrophy and hyperplasia of the endometrium is almost always demonstrable in these cases, but it is also often present when there is no menstrual abnormality, and occasionally, in spite of the fact that there is free bleeding, atrophic instead of hypertrophic changes occur.

Whenever there is a demonstrable local cause for hemorrhage, such as lacerations, displacements, tumors, etc., treatment is simple and easily determined on. Indications for operation are obvious and the extent of the operation is determined by the amount of disease. In all cases in which the uterus is not to be removed, curettage should always be performed, as this hastens the return to normal. These easily recognized and treated forms of hemorrhage occur with greatest frequency during the child-bearing period and a large number of them are a direct result of parturition.

Puberty and the menopause furnish us with the most difficult and puzzling forms of hemorrhage and the ones which are at the same time the most resistant to treatment.

The onset of the menstrual cycle is a critical period in a girl's life, when her nervous and bodily functions are readily and perhaps permanently unbalanced. The greatest care is necessary in the treatment of any abnormalities of sexual organs, as nervous shocks of any kind are likely to develop a morbid mental attitude toward the menstrual and sexual life. Pelvic examinations and local treatment can and should be avoided in all but the most exceptional cases. This applies even to patients who have been anesthetized. It is a question if anesthesia is advisable, because the preanesthetic and postanesthetic periods are usually associated with the rapid development of fanciful ideas which may have a lasting effect on the sensitive mental organism of the adolescent. Delay in resorting to examination and explanation by the patient's mother of the object of the examination, with a minimum of manipulation at the time, are better safeguards than anesthesia in all but exceptional cases. Rectal examination may sometimes be substituted for vaginal.

Hemorrhage at puberty, the so-called virginal menorrhagia and metrorrhagia, may of course depend on a local cause, such as infection, ovarian disease, etc., but such cases are comparatively rare. The majority are cases of "essential" hemorrhage.

---

* Read in the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913

The causes of these essential hemorrhages are numerous and varied. Sufficient mention has already been made of the common constitutional causes, although mitral stenosis probably deserves special mention. Hemophilia, which, contrary to general belief, is not uncommon in a mild form among women, may manifest itself by uterine hemorrhage at puberty; I have seen this prove fatal. So, too, chlorosis and congenital syphilis may cause irregularities at the onset of menstruation.

A factor in menstrual hemorrhage that is worthy of more consideration than it receives at present is the estimation of the calcium index. There is undoubtedly a close connection between the calcium metabolism and menstruation (Blair, Bell). Hyperthyroidism is another cause of increased and irregular bleeding at puberty.

Anomalies of ovarian function in regard to its internal secretion are frequently accused of causing menstrual irregularities in early life. Dalche's explanation is that rapid growth of the body and sudden development and maturation of the ovary unsettles the normal equilibrium and causes a condition of "ovarian ataxia" in which periods of hyperfunction alternate with periods of functional inactivity. This form of "ovarian" hemorrhage is not to be confused with that due to macroscopic disease of the ovaries.

It is apparent that there are two distinct sides to the treatment of uterine hemorrhage at puberty; one the treatment of cause and the other treatment of the acute condition, as at times bleeding is so free that the patient's health is markedly affected.

Treatment of the underlying cause varies in the individual case. No definite rules can be determined on. Girls with a low calcium index should receive from 10 to 20 grains of calcium lactate three times a day. This is the only drug that can be said to have a definite indication, although the list of drugs used is of formidable size, some being administered with the idea of overcoming the underlying cause, others to stop the hemorrhage. Among these may be mentioned ovarian, adrenal, thyroid and pituitary extracts, animal serum, ergotin, hydrastin, stypticin, etc.

The starting place in the treatment of these cases of "essential" uterine hemorrhage is the axiom that such a case should never be curetted. The most essential part of the immediate treatment is rest in bed. Nothing tends to control hemorrhage so effectually. Many men order in addition hot vaginal douches. This is justifiable in married women, but, like all other forms of local treatment, should be avoided in unmarried girls. If it is desired to have the local effect of heat it is best obtained by hot rectal injections, and it is questionable if even these are advisable, as the application of an ice-bag to the abdomen is much more efficacious.

In this connection I should like to state my conviction that routine vaginal douches do more harm than good in most instances. They are one of the many forms of local treatment that increase the number of women suffering from the various sexual psychoneuroses. Many women, married and unmarried, can trace the development of sexual types of mental abnormalities to well-meant but injudicious local treatment. Women doctors are marked offenders in this direction with frequent, unnecessary vaginal examinations, weekly changes of pessaries, and the routine prescription of self-administered vaginal douches. Digital massage of the uterus is a favorite treatment of some osteopaths, with what disastrous results can readily be imagined.

The use of x-rays, which might be expected to have some influence on these cases of hemorrhage, is contraindicated because of their destructive effect on the ovaries. In hyperthyroidism ligation of the vessels or excision of part of the gland might be expected to result beneficially, and that they do not is probably because the symptoms are due more to disordered than excessive secretion. There is a strong reaction against thyroid operations in early life, at least until prolonged and intelligent attempts have been made to control symptoms by hygienic treatment. Gelatin given subcutaneously or by mouth has been recommended. Its use by the former method is dangerous from the standpoint of sepsis, and the latter method is uncertain, although it is said to increase the coagulability of the blood. Electricity is objectionable because it is a form of local treatment.

It seems that we are reduced, therefore, to the effects of rest, quiet, free action of the bowels, ice, calcium, or other drugs as they seem to be indicated; and, above all, the beneficial effects of time, for improvement or cure of these obstinate cases of uterine hemorrhage at puberty.

Again let me sound a warning against curettage and other forms of local treatment. They not only do no good but are distinctly harmful, and are the basis of many of the psychoneuroses that our friends the psychiatrists are revealing to us out of the old order of surgical neurasthenia.

Hemorrhage at the menopause presents problems of a different nature. Irregular and excessive bleeding at this time puts on the attending physician the burden of proving the absence of carcinoma of the cervix or body. For this reason curettage is indicated—in fact, it is imperative—in every case of this description, as it is by this means only that carcinoma of the body can be ruled out. Inspection and section for microscopic examination suffice for the diagnosis of cancer of the cervix.

The treatment of these forms of hemorrhage consists in as complete a panhysterectomy as possible. But these are not the cases that cause trouble and anxiety in diagnosis and treatment. There is a class in which physical examination shows little or no abnormality in the uterus and its appendages; curettage reveals a normal endometrium or a moderate amount of simple endometritis, yet the bleeding continues and becomes more instead of less frequent and severe. These are the cases that have caused the adoption of numerous methods of treatment, all aiming to avoid the necessity for hysterectomy.

The cause usually given for the hemorrhage is sclerosis of the uterine vessels, distinct from and not to be confused with a general arteriosclerosis. The greatest change is in the adventitia and media. The adventitia is greatly increased by the deposit of fibrous tissue, which also involves the surrounding tissue, giving rise to a peri-arteritis. The media is diminished in size because the muscle is replaced by fibrous tissue. The intima is not involved and the lumen of the vessel not encroached on, a differential point from syphilitic atheroma.

This sclerosis may exist independently or be associated with more or less intermuscular fibrosis, which may go to the length of supplanting a certain amount of muscular tissue. These variations in the pathology probably account for the difference in the physical signs in individual cases. In some the uterus is small and apparently normal to examination, in others it is large and soft, and in still others it is large and very firm. The sclerosis of the vessels is common to all three forms and is believed to be the offending agent in the causation of hemorrhage. Simpson believes that the condition of the myometrium plays a greater rôle in the regulation and prevention of hemorrhage from the uterus than the vessels. The sclerosis observed in these cases could readily so interfere with the tonic contraction of the uterine muscle as to prevent occlusion of the vessels by muscular action and thus permit excessive loss of blood.

The various means that have been employed to overcome bleeding of this description have as their object preservation of the uterus and the maintenance of the normal menstrual flow. This is of course an advantage in younger women, in whom this condition is said to occur with greater frequency than at first supposed.

Curettage is always the first step in the treatment of these cases, to enable one to exclude carcinoma. On this point every operator is agreed. Subsequent treatment marks the particular predisposition of the individual surgeon.

To mention non-operative methods first, the x-ray and electricity are the most prominent contenders for popular favor. Several observers have had varying degrees of success in controlling hemorrhage by the use of x-rays. They act by causing atrophy of the ovaries and subsequent atrophy of the whole genital tract, including the uterus. For cases in which operation is refused or contra-indicated there is no doubt that the x-rays offer a fairly satisfactory method of treatment, but in my experience one not always to be relied on. There is a fairly large percentage of failures and thus valuable time may be lost. On account of their effect on the ovaries, the x-rays cannot be used on young women.

Electrical treatment has various advocates (particularly Hirst). I have had no experience with it except in meeting cases that have relapsed after a more or less prolonged period of freedom from symptoms after a course of electrical treatment. I have never been able to persuade myself that there is any field for such treatment.

Atmocausis, the application of live steam to the uterine cavity, has occasional advocates in various parts of the world, who are all positive in their statements that good results can be obtained by its use, particularly in cases that occur during the child-bearing period. when radical treatment is to be avoided if possible. In these cases the endometrium is cooked, but not sufficiently to cause subsequent sloughing. At times destructive atmocausis is undertaken with the view of causing complete occlusion of the uterine cavity by sloughing and subsequent adhesion.

The action of the steam is difficult to regulate to just the required degree and the prevention of infection is almost impossible. I myself have no faith in the ability to cure by atmocausis any but the very mildest cases of hemorrhage and feel sure that any field of usefulness it has is extremely limited. I never use it.

Of other forms of treatment, hot air, vibratory massage, active and passive hyperemia, zinc injections and animal serums I have had no experience. It would be impossible for any one man to try all the methods that have been advocated, and each operator must work out for himself his own views.

Occasionally one of these patients bleeds so freely that immediate local treatment is necessary. Plugging the uterine cavity and vagina with gauze will always stop the bleeding, but should be done only when asepsis is sure. Under other circumstances a vaginal plug, firmly pushed home into the vaginal fornices, is safer and practically as certain of stopping hemorrhage.

Most of the obstinate cases of uterine hemorrhage that fall into my hands have been the rounds of various "specialists," who have put them through all the different recognized and unrecognized forms of local, general and absent treatment. These patients come to me with a vigorously expressed desire for cure, having been thoroughly disgusted by the time and money they have wasted without getting relief.

Naturally these represent the failures of other treatments, and it may be that my experience has made me too skeptical of the value of forms of treatment other than operative, as I never encounter the successes of the conservative methods.

I believe that in a well-marked case of uterine hemorrhage due to sclerosis of the vessels, complete removal of the uterus is the only sane treatment.

I wish particularly to direct attention to the advantages of a preliminary hysterotomy in certain cases. I advocated a year ago in this Section hysterotomy as the operation of choice in placenta praevia; in occasional neglected cases of the toxemia of pregnancy and in certain cases of menorrhagia and metrorrhagia in which carcinoma and gross disease of the uterus appeared not to be a factor. By thus opening the uterus I have on several occasions disclosed a nonmalignant polypoid condition of the endometrium which could be much more thoroughly treated under direct inspection than by blindly curetting from below through the os. Occasionally, also, one or more fibroid nodules may be discovered beneath the endometrium and removed with ease. The usual method of curetting could hardly be successful in the removal of these small submucous myomas. I have had no mortality from hysterotomy and believe it to be an operation deserving of wider application. Practically the only danger of any moment is that of infection of the abdominal cavity. If the uterus and the field of operation be well walled off with gauze pads this danger may be minimized, even in the presence of an infected uterine cavity. It must be remembered that the operation of hysterotomy, partial or complete, is not free from the dangers of infection. Still, I would not venture hysterotomy in the case of a boggy uterus evidently the seat of metritis. This condition is rare, however, and it is my belief that the risk of infection following hysterotomy is greatly magnified by the objectors to the operation. Having had great satisfaction from the operation in selected cases, I do not hesitate to employ it and to recommend it to experienced surgeons.

The question of the desirability of complete hysterectomy is settled by the patient's age, degree of uterine disease and the chances of the subsequent development of carcinoma. In women of 40 or over I never hesitate to do the complete operation, as the uterus is of no actual use to most women of this age. I remove the ovaries at the same time, as they may be the cause of symptoms, and, while they cannot cause hemorrhage after the removal of the uterus, they are still a potential menace to subsequent good health by their tendency to tumor formation and the possibility of the perversion of their internal secretion. Occasionally in operating for a supposed uterine cause of hemorrhage one finds an ovarian hematoma or hemorrhage into a lutein cyst, which is probably the fundamental cause of the hemorrhage. I do supravaginal hysterectomy and appendectomy in these cases.

SUMMARY OF CASES STUDIED

The total number of cases studied was 227.

Sixty-nine cases of fibromyoma uteri and 2 cases of carcinoma uteri which never presented symptoms of menorrhagia or metrorrhagia.

Forty-five cases, pathologic diagnosis of endometritis. Operations performed: complete hysterectomy in 5 cases (past menopause); anterior hysterotomy and curettage in 1 case; vaginal hysterectomy in 2 cases; dilatation and curettage in 37 cases.

Twenty-one cases, pathologic diagnosis of fibromyoma with endometritis. Operations performed: supravaginal hysterectomy in 17 cases; complete hysterectomy in 3 cases; vaginal hysterectomy in 1 case.

Twenty-four cases, pathologic diagnosis of carcinoma. Operations performed: complete hysterectomy in 12 cases; supravaginal hysterectomy in 4 cases; dilatation, curettage and cauterization in 1 case; dilatation and curettage in 1 case; cauterization in 1 case; vaginal hysterectomy in 1 case; 4 cases inoperable.

Forty-four cases, pathologic diagnosis fibromyoma. Operations performed: supravaginal hysterectomy in 31 cases; complete hysterectomy in 7 cases; anterior hysterotomy in 2 cases; myomectomy in 3 cases; vaginal hysterectomy in 1 case.

Two cases, pathologic diagnosis sarcomatous degeneration of fibroid uteri, supravaginal hysterectomy being performed in both cases.

Mortality.—Four deaths, all occurring in cases of carcinoma. In one carcinoma also involved the sigmoid and the patient developed fecal fistula; one patient died of uremia and two of toxemia.

1634 Walnut Street.

ABSTRACT OF DISCUSSION

DR. LEWIS S. MCMURTRY, Louisville: A point on which I would differ from Dr. Deaver is regarding anesthesia of virgins for examination of the uterus. It is practically impossible to make a satisfactory examination without anesthetizing the patient. She is unable to control the voluntary muscles and the resistance is such that examination is impossible. I would emphasize Dr. Deaver's statement that hysterotomy should be a means for diagnosis only in the hands of experienced surgeons. In the hands of men accustomed to opening the abdomen every day it is a safe procedure. and in many cases it is justifiable. As a routine procedure it would be a very dangerous practice. All of us who have operated for fibroma have opened the uterus to find that all the hemorrhage was caused by a small polyp in the fundus and that hysterotomy would have reached it. Hysterotomy as an exploratory operation for cancer of the uterus is seldom necessary.

Dr. Deaver rendered special service in calling attention to two salient points: (1) that this symptom should be dealt with as a symptom; (2) that there should be a thorough investigation made of every woman who has a persistent uterine hemorrhage to find the pathology and deal with it in a surgical way. I would especially commend the suggestion which Dr. Deaver makes as to young women at puberty, who have persistent hemorrhage without demonstrable lesion of the uterus or its appendages. Rest and general systemic treatment should be observed rather than resort to indiscriminate dilatation and curettage and other active surgical treatment. In conclusion, it is neccessary to reiterate the oft-repeated warning as to the vicious practice of resorting to the curet indiscriminately for uterine hemorrhage. Curettage is more abused to-day than any other surgical operation and does more harm.

CLINICAL NOTES ON PATIENTS FROM THE MIDDLE NORTHWEST INFECTED WITH ENTAMEBAS *

H. Z. GIFFIN, M.D.
Attending Physician to the Mayo Clinic
ROCHESTER, MINN.

In 1911, Sistrunk[1] published our earlier experience at the Mayo Clinic with regard to the finding of intestinal parasites in individuals residing in the middle Northwest. Since then the examination of the stools in certain cases has led so frequently to the identification of entamebas that we have come to consider this infection as a relatively common one. In the diagnosis of the different types of amebas present, Craig's[2] description of the morphologic characteristics has been followed in our laboratories by Sistrunk and Sanford. Moreover, the recent work of Darling[3] and Craig[4] on the identity of *Entamoeba tetragena* with *Entamoeba histolytica* inclines us to prefer to group cases in which a morphologic diagnosis of either one of these parasites was made as *Entamoeba histolytica*. In this review, however, the former distinctions between *tetragena* and *histolytica* are maintained because of any interest that may remain in connection with the morphologic type of those amebas found in the Northern states.

During the last two and one-half years the stools of 1,700 patients have been examined for parasites. Entamebas have been found in 227 of these, or 13 per cent. Of this number, 148 were diagnosticated as *Entamoeba coli* and 79 as *Entamoeba tetragena* or *Entamoeba histolytica*. These totals include patients from all parts of the country who have been under our observation. This consideration, however, will be confined entirely to those with residence in Minnesota, Iowa, Wisconsin, North and South Dakota, Montana and Nebraska, whose infection, as nearly as can be judged, was not obtained in the South. Most of these patients had never been in the South. A few had traveled in the South but their visit seemed to have no relation to the onset of their symptoms. The first part of this paper is concerned with a consideration of those cases in which *Entamoeba tetragena* and *Entamoeba histolytica* were present; the latter part with a consideration of the cases showing *Entamoeba coli*.

CASES IN WHICH ENTAMOEBA TETRAGENA OR ENTAMOEBA HISTOLYTICA WAS FOUND

Of the seventy-nine patients showing *Entamoeba tetragena* and *Entamoeba histolytica*, forty-one, or a little less than one-half, evidently received their infection while residing in the before mentioned states and therefore constitute the most important group for our immediate consideration. Of this number, there were from Minnesota 14, Iowa 12, North Dakota 5, South Dakota 5, Nebraska 2, Wisconsin 2, and Montana 2.

Of the forty-one patients, thirty-six showed *Entamoeba tetragena* and only six *Entamoeba histolytica* (one of these, a patient with very severe symptoms, showed both *tetragena* and *histolytica*). It is therefore a prominent fact that the parasite of predominance conforms morphologically to the description of *Entamoeba tetragena*. In those cases showing *Entamoeba histolytica* the parasites were more numerous, though it is quite certain that these patients did not receive their infection in the South.

In a consideration of the clinical symptoms of these cases the original chief complaint of the patient becomes an interesting basis for classification.

Group 1. Patients complaining chiefly of diarrhea.—Twenty-four of the forty-one patients complained chiefly of diarrhea. Thirty-five patients of the forty-one, however, gave a history of diarrhea, although in some of these it was not their chief complaint. Thirteen had had, at one time or another, severe attacks of diarrhea with more or less blood in the stools. As nearly as can be judged, however, these attacks were not so violent as those in cases reported from the South. On the other hand, most of our patients gave a history of more or less constant diarrhea of a mild type, also quite in contrast to the Southern cases. More than one-half the patients gave a history of the passage of macroscopic blood at one time or another in the course of their disease.

Group 2. Patients presenting themselves chiefly on account of abdominal pain.—A second group of cases consists of those patients who complained chiefly of abdominal pain, nine in number. It has been our custom to send patients complaining of indefinite abdominal symptoms for a stool examination and the finding of parasites in this group of cases is due to that routine. The findings, of course, may be accidental, although at least two patients of this group are well of their original complaint.

Three-fourths of the patients (thirty-two) gave abdominal pain as a minor complaint. Pain was not confined to the lower abdomen; ten of the number suffered from upper abdominal pain and six complained of pain in the right lower quadrant, suggesting the possibility of involvement of the cecum. Rectal pain was a prominent symptom in four patients.

Group 3. Those complaining of indefinite gastric symptoms.—Patients complaining of indefinite gastric symptoms have often been referred for stool examination. Three patients in the series, who consulted a physician chiefly on account of gas and sour eructations, nausea and epigastric distress, have shown pathogenic entamebas. Complaint of this character, however, is not uncommon in the other cases. Fifteen of the forty-one patients gave a history of gastric symptoms, although they complained chiefly of abdominal pain or diarrhea. Nausea seems to be quite commonly associated with the more severe attacks, eleven of the series volunteering this information.

Group 4. Patients with constipation.—It is rather not to be expected that *Entamoeba tetragena* should be found in patients complaining chiefly of constipation and without diarrhea. In two instances of this character, however, amebas were easily demonstrated. Intermittent constipation, even in connection with those cases showing severe diarrhea, is not an uncommon finding.

Group 5. Miscellaneous cases.—In the remaining three cases dyspnea and weakness were given as the chief complaints and were the result of severe anemias. Two of these anemias were definitely of the pernicious type, while one was of doubtful nature and may have been entirely secondary. The finding of entamebas in cases of pernicious anemia can only be regarded as accidental.

Only one case of abscess of the liver has been observed among patients from the middle Northwest. In this instance *Entamoebae histolyticae* were demonstrated in the stools; the abscess, which was drained, was of typically amebic character. The patient resided in Duluth, had never been in the South and gave a six weeks' history of diarrhea with bloody stools. It is not certain that this patient received his infection in Minnesota. He had emigrated from Russia six months previously but his history had been of only six weeks' duration.

The duration of the history relative to the bowel symptoms for the entire group of forty-one patients varied from six weeks to twenty years. In six of the patients it was longer than ten years, in ten over five years, while in seventeen it was less than a year; the average was four years.

The eosinophil count was low. Three of the series showed no eosinophils on differential count; the average in twenty-one counts was only 2.5 per cent. In this connection it may be of interest to note that thirteen patients have been sent to the laboratory on account of a very high percentage of eosinophilia in order that a search for parasites might be made and in all of these instances the results were negative for entamebas.

Proctoscopic and sigmoidoscopic examinations were obtained in twenty-three of the forty-one patients. In sixteen they were negative, in three a diffuse colitis was demonstrated, in two a granular colitis and in two ulceration. Those cases showing ulceration and diffuse or granular colitis were all infected with *Entamoeba tetragena*. It should be remembered that a negative proctoscopic examination may not necessarily mean a negative colon, as the disease may be localized at one of the flexures or in the cecum. It is quite likely, however, that the large number of negative examinations is at least another indication of the mild character of these cases in comparison with the infections in the South. From the patient's point of view, however, they are severe enough to be a great inconvenience and detrimental to the general health.

The parasites were usually demonstrated at the first examination. In thirty-one instances amebas were found at the first examination, in nine two examinations were necessary and in one case three examinations. It is also evident, therefore, that the search for parasites should not to be abandoned too early. In the case in which three examinations were necessary for a demonstration of the parasites the patient had complained of intermittent attacks of diarrhea with bloody stools for four years.

CASES IN WHICH ENTAMOEBA COLI WAS DEMONSTRATED

As formerly stated, *Entamoeba coli* was reported in 148 patients. Of these, 106 were in patients residing in the middle Northwest. Fifty-nine, or over one-half of these patients consulted a physician chiefly because of diarrhea, while in sixty-nine or two-thirds of them diarrhea was given as one of the principal complaints. One showed granular colitis, eight diffuse colitis and four ulcerative colitis on proctoscopic examination. Of those presenting themselves chiefly on account of diarrhea, one-third gave a history of more than five years' duration, nine more than ten years and four more than twenty years. In many of them the diarrhea was severe in character. Thirty-eight or over one-third showed red blood-cells on microscopic stool examination, while sixteen gave a history of macroscopic blood. The parasites were usually found at the first examination. In only seven of the 106 patients was a second stool examination necessary for the demonstration of the amebas.

We have no data on which to base a discussion of the possible pathogenicity of *Entamoeba coli* either positively or negatively, and present these facts only as statements of our findings.

The presence of *Entamoeba coli* in the more severe cases need indicate no etiologic relationship on the part of these organisms. And again it is quite likely that a further search for parasites would have demonstrated the presence of *histolytica* also in some instances; several of our more recent cases showed *Entamoeba coli* at the first examination and *Entamoeba histolytica,* as well as coli, subsequently.

TREATMENT

It has been very difficult to obtain an approximately accurate idea of the results of treatment in this series of cases. It has generally been necessary for the patient to return to his home where the treatment was carried out under the care of the family physician. Ipecac alone was used in 75 per cent. of the cases in which treatment seemed advisable. Ipecac was administered in conjunction with coal-oil enemas to eight patients. This does not take into account the treatment of those patients residing elsewhere than in the middle Northwest. Enemas of kerosene (Hanes[5]) alone were used under our observation in four instances in which *Entamoeba tetragena* or *Entamoeba histolytica* was present (one of these showed ulcerative colitis), and in all of them the results were excellent. It is our impression that coal-oil enemas should be given a trial in cases of entamebic infection in order that we may learn something more definite with regard to their efficacy. The administration of emetin hydrochlorid is considered by many observers of large experience to be almost specific in its action, and is especially indicated in severe types of infection (Rogers[6]).

It may be emphasized that amebas are generally demonstrated easily at the first examination if the patient be properly prepared and the stool properly obtained. Epsom salts may be given early in the morning and an hour or two later the patient reports at the laboratory where one or more stools may be examined while they are yet warm. It is a noticeable fact that the search may be difficult either in a stool that is too well formed or in one which is too watery.

It may be well to urge a more wide-spread interest in the examination of stools for parasites in the Northern states. Undoubtedly entamebic infection is a quite generally unrecognized cause of diarrhea, and probably of certain indefinite abdominal complaints. At the same time it should be remembered that the finding of parasites can be regarded only as a part of the evidence in the diagnosis of any condition of the bowel; there may be a tendency to ascribe a patient's complaints too quickly to this finding.

ABSTRACT OF DISCUSSION

Dr. Van G. Yeager, Hayward, Wis.: I practiced formerly in Lake Charles, La. In that particular section of the country we have a great deal of amebic dysentery. I recall one case in which the patient passed, on an average, from fifteen to twenty stools in twenty-four hours. When he came to my office his stool consisted entirely of mucus and blood, and on examination I could find from five to ten amebas in the one-sixth field. If the patient is given a good dose of magnesium sulphate in the morning, without any breakfast, it will be possible to obtain a stool thin enough, in most instances, to demonstrate the ameba without difficulty.

In amebic infections in the early stage, there is probably always a marked eosinophilia, but when the infection has lasted sufficiently long to give marked symptoms the differential count is often of little value, for whatever the increase in eosinophils means, and it probably indicates a fight against poisons from intestinal infections with parasites, it surely approaches the normal as the system becomes accustomed to the poisons which produce it.

I have treated probably ten or fifteen severe cases of this kind. Ipecac gave satisfactory results in all. Dr. Simon in the Charity Hospital in New Orleans uses five-grain salol-coated pills, giving from 60 to 100 grains each night for a week. The salol coating is not dissolved in the stomach, but in the intestine where the effect of the ipecac is wanted, and thus the nauseating effect which would result from such enormous doses of ipecac in the stomach is avoided. To avoid the taking of much medicine some pharmaceutical houses have placed in the hands of physicians who are in positions to make careful observations a preparation of emetin which is given hypodermically with success. Most patients will be nauseated, aside from the ipecac, just from taking a great deal of medicine. By giving paraldehyd, which is one of our safest hypnotics, immediately after the ipecac, the patient will sleep until the ipecac has had time to be effective. I recall one patient who vomited frequently during the first few hours after taking ipecac. I advised him to take paraldehyd, which he did, sleeping soundly afterward for about six hours; he vomited immediately on awakening, however. This is a common experience.

Dr. Charles L. Minor, Asheville, N. C.: I wish to ask if the 100 grains are given in one dose, or in a number of doses during the twenty-four hours?

Dr. Van G. Yeager, Hayward, Wis.: The 100 grains are given in one dose at night. This treatment is carried out for a week, the patient being given from 60 to 100 grains each night and being kept on a light diet and in bed. One advantage of a light diet is that the bowel is empty, and the ipecac comes in contact with the ameba.

Dr. W. C. Dixon, Nashville, Tenn.: In the South we see many cases of amebic dysentery. I have used the ipecac treatment, giving large doses, but it is exceedingly unpleasant. I have not been so successful in avoiding the nausea as the doctor seems to have been in his cases. I have recently been able to secure emetin hydrochlorid and have obtained good results from its use. Previously, I used the emetin resinoid in solution. This is the most satisfactory treatment for dysentery with which I am familiar. The dosage of the hydrochlorid is one grain in twenty-four hours, given under the skin of the arm; the effect is almost magical in acute cases, or in chronic cases with much ulceration and many amebas in the stools. In the course of three or four days most of these cases clear up. It has been far more satisfactory than irrigation with quinin, coal-oil or any other agents that have been used. It is easy to give. The patients do not necessarily go to bed, although it is probably better if they are kept in bed and on a liquid diet. They are given one-fourth of a grain of the emetin one day, half a grain the next day, a grain the next day, and a grain each succeeding day. At the end of three or four days the stools are usually free from amebas and the patient makes an uninterrupted recovery.

The credit for this treatment is due to Dr. Rogers of Calcutta, India. He has had an extensive and satisfactory experience with it. He seems to have cured a number of patients with abscess of the liver by aspiration and injection of emetin into the cavity, together with the hypodermic administration of the emetin. I have had only one case of abscess of the liver in which I used emetin. The patient was in an extreme condition, the abscess was aspirated and one grain of emetin in solution was injected into the cavity. The patient showed some improvement for a few days, and then died rather suddenly. At necropsy it was found that he had two abscess cavities in the liver, the upper one having ruptured into the pleura, the lower one having been aspirated.

[6] Rogers: Brit. Med. Jour., June 22, 1913, pp. 1424-5; ibid, Aug. 24, 1912, pp. 405-9.

DR. G. D. HEAD, Minneapolis: We have a form of chronic diarrhea in the North, occurring in persons who have never been in the South. It is due to some intestinal parasites of which Dr. Giffin has spoken. There is, however, a form of diarrhea of which I have seen many cases, in which one finds in the stools the *Trichomonas intestinalis.* This form of chronic diarrhea lasts for years and simulates quite closely the diarrhea due to *Ameba coli.* Tremendous numbers of these flagellates are often found in the stools. They are recognized immediately with a one-sixth objective. If the flagellates can be gotten out of the stools, the diarrhea, as a rule, ceases. We find, however, great difficulty in killing them out. I am sure that this is a chronic form of diarrhea endemic in the North. I do not know where the flagellates come from. Even Dr. Giffin gives no explanation as to how the entamebas get into the stools in the North. When a physician meets a case of chronic diarrhea in the North, he should examine the stools as systematically and carefully as the physician in the South.

DR. W. V. BREM, Los Angeles, Cal.: Dr. Bass has been using emetin hypodermically in the treatment of experimental amebic infections and prophylactically in quite a number of patients. He believes that of all the specifics in medicine emetin is probably the best against amebic infection.

Some time ago in reporting the result of the use of ipecac in amebic dysentery in Panama, I discussed at length the bismuth treatment as used by other men in Panama, and I expressed considerable doubt about its efficiency. I have recently examined the stools of a patient who was under treatment with ipecac according to the method that I felt to be the best. The treatment had no effect on the infection so far as eradication of the amebas was concerned. The patient was then put on the bismuth tratment, which immediately cleared up the infection. Darling, in Panama, has recently reported that he examined the stools of twenty-eight patients who had had amebic dysentery and been treated with bismuth. He found amebas in only one instance. The bismuth treatment of Deeks and Shaw may, therefore, be quite effectual in the treatment of amebic dysentery.

DR. W. W. TOMPKINS, Charleston, W. Va.: Will Dr. Giffin give the details of the coal-oil injection? It seemed to be satisfactory in all the cases.

DR. H. Z. GIFFIN, Rochester, Minn.: I shall answer only the question concerning the coal-oil treatment. Kerosene enemas have been used in the treatment of entamebic infections for four or five years. I have employed them alone in only a few cases, but with satisfactory results. After a few injections it was impossible to find the parasites. This is the reason I suggest that possibly this treatment should be given a further trial. After the large bowel is cleansed, about one quart of coal-oil is injected. The patient retains it for fifteen or twenty minutes, sometimes longer. The treatment is repeated about twice a week. There is no abdominal complaint whatever. The only irritation is possibly at the rectum, and this is easily overcome by using a small amount of petrolatum.

DR. W. W. TOMPKINS: What is meant by coal-oil? Does it mean simply kerosene?

DR. H. Z. GIFFIN: It means kerosene.

SARCOMA OF THE CHORIOID

A CASE WITH METASTASIS TO THE LIVER EIGHT YEARS AFTER ENUCLEATION OF THE EYE

AARON BRAV, M.D.
Ophthalmologist to the Lebanon Hospital
PHILADELPHIA

Sarcoma of the chorioid endangers not only the visual organ, but also life. When the eye is removed the prognosis as to life is absolutely grave. Even after the eye is removed life is still in danger, for it is impossible to foretell whether or not sarcomatous cells have been carried, prior to the enucleation, into the deeper tissues of the body. When the sarcoma is removed late in the course of the disease there is often a recurrence of the condition in the enucleated orbit, which eventually is the cause of death. If the eye is enucleated early, however, there is usually no recurrence locally, but the patient is still not free from the danger of metastasis. The case here reported shows a metastatic growth making its appearance eight years after the eye has been enucleated.

Miss A. L., aged 18, consulted me Feb. 5, 1905, on account of failing eyesight. Her left eye had been gradually failing for about two months. She felt otherwise well. She had a good family history. Examination showed both eyes quiet and free from any inflammation; right eye, perfectly normal; left eye, cornea normal; pupil 6 mm.; no reaction to light; vision equal to light perception.

Ophthalmoscopic examination showed a dark media and no fundus reflex. With a plus 7 lens several blood-vessels were seen over a grayish retina, which was detached. The eyeball was slightly prominent as compared to the right eyeball. The diagnosis was retinal detachment with a suspicion of a chorioidal tumor as the etiologic factor.

February 8: The eyeball protruded and tension was plus 2. Eye was somewhat painful on pressure and patient had headaches. I informed the patient of the gravity of the situation and advised an enucleation. Dr. Schwenk in consultation agreed with me. The patient, however, would not submit to an enucleation.

May 30: The patient returned with badly inflamed eye, severe pain and tension plus 3. The severe headache was evidently caused by the high intra-ocular pressure. Again I insisted on enucleation. She consented only after repeated warning on account of the danger to life.

June 8, 1906: The eyeball was enucleated and examined. A pigmented tumor the size of a small hazelnut was found at the posterior pole. Microscopic examination showed the tumor to be a melanotic sarcoma.

July 6: An artificial eye was inserted. No local recurrence followed and patient was well. She married in 1909 and gave birth to a healthy child.

Jan. 12, 1912: The patient consulted me on account of a conjunctivitis, which readily yielded to treatment. Otherwise the patient was in good health.

Jan. 3, 1913: The patient gave birth to another child. After delivery the family physician, Dr. Jacob, noticed an enlargement of the liver, which increased rapidly. Dr. Tyson was called in consultation and diagnosed a malignant growth of the liver. At the special request of the patient and family, and with consent of the attending physician, I saw the patient, January 10. I found her in bed, markedly emaciated and yellowish pale in color. The liver was very large, coming down below the umbilicus, filling in practically the entire abdominal cavity. The growth was lobulated. Four distinct lobules could be felt. The patient was very weak. She died May 6. No post-mortem was obtainable. The diagnosis, however, was clear.

The case is of considerable interest and shows that in sarcoma of the chorioid metastatic growths with a fatal termination may occur at any remote period after the eye has been enucleated, even though the tumor did not recur locally. It further emphasizes the absolute necessity of early diagnosis and prompt removal of the eye in order to save life.

Necessity of Vital Statistics for Control of Contagious Diseases.—A community which has no means of knowing with what contagious diseases it is afflicted, nor how many cases there are, nor where they are, is helpless to protect itself, and unnecessary sickness and death will result.—Assistant Surgeon-General Trask.

Special Article

ELEVENTH ANNUAL SUMMARY OF FOURTH OF JULY INJURIES

This week, for the eleventh consecutive year, THE JOURNAL presents statistics of deaths and injuries resulting from the celebration of the Fourth of July, with particular reference to tetanus or lockjaw resulting from these injuries. With the rapid decline in the number of casualties in the last few years, instead of relaxing its vigilance THE JOURNAL has made extra effort to secure complete and accurate data. As reported last year, a large majority of the blanks were returned from hospitals with the statement that no cases were treated. From others only a few names were reported, whereas in previous years several pages were required to contain the lists. Our thanks are extended to health officers, hospital superintendents, physicians and others for the careful reports which have made these statistics practically complete and the figures fairly reliable. The data are presented in the same manner as heretofore so that the comparison with the figures of previous years may be made.

FEWER CASES OF LOCKJAW

Only four cases of tetanus were reported this year as compared with seven last year, eighteen in 1911, seventy-two in 1910 and 150 in 1909. The returns this year are most encouraging and give hope that deaths from this senseless cause will soon cease.

TABLE 3.—RATIO OF TETANUS CASES TO BLANK CARTRIDGE INJURIES

Year.	Tetanus Cases.	Blank Cartridge Injuries.	Ratio.
1913	4	97	1:24.25
1912	7	75	1:10.71
1911	18	185	1:10.28
1910	72	450	1: 6.25
1909	150	1,225	1: 8.17
1908	76	942	1:12.39
1907	73	606	1: 8.16
1906	89	979	1:11.00
1905	104	809	1: 7.78
1904	105	905	1: 8.62
1903	417	1,672	1: 4.27
Totals	1,115	7,945	1: 7.12

The ages of the four lockjaw patients this year were 15, 14, 12 and 11 years, respectively, and all were boys. In three cases the injury was on the hand; in the other the site was not given. The length of time between injury and death was six days in one and seven days in another. In the third case the dates were not given by which the time could be computed, and in the fourth patient (who recovered) the time between the injury and complete recovery was thirty-one days. The figures in parentheses (Table 1) give the number of days between the time of injury and the appearance of active symptoms of tetanus, this being in four and eleven days, respectively. In the patient who recovered, antitoxin was first used on the eleventh day, when active symptoms appeared. The long incubation period would seem to indicate a germ of feeble virulence, which may partly account for the recovery. The list of tetanus cases is given in Table 1.

TABLE 4.—CAUSES OF TETANUS CASES

Year.	Blank Cartridge.	Giant Cracker.	Cannon.	Fire-arms.	Powder, etc.	Total.
1903	363	17	5	3	29	417
1904	74	18	5	1	7	105
1905	65	17	4	5	13	104
1906	54	17	1	7	10	89
1907	52	8	6	4	3	73
1908	58	5	4	3	6	76
1909	130	9	1	4	6	150
1910	64	2	..	5	1	72
1911	15	1	1	..	1	18
1912	7	..	..	..	..	7
1913	4	..	..	..	..	4

DISTRIBUTION OF TETANUS

The tetanus cases by states are shown in Table 2. Cases occurred in only three states this year as against six states last year, ten states in 1911, eighteen states in 1910 and twenty-five states in 1909. Two of the cases occurred in New York and one case each occurred in Indiana and Kansas.

THE DEADLY BLANK CARTRIDGE

Blank-cartridge wounds, which have always been responsible for a large majority of tetanus cases, this year caused all four cases. With a full knowledge of this fact and of the awfulness of the deaths from lockjaw, there should be no relaxation in the restrictions against the use of blank-cartridge pistols.

As may be noted on comparison of the statistics of this year with those of previous years (Table 3), there is a significant ratio each year between the number of tetanus cases and the number of blank-cartridge wounds. A larger number of blank-cartridge wounds almost invariably brings also a larger number of cases of lockjaw. The smaller number of tetanus cases in recent years in proportion to the blank-cartridge injuries is doubtless due to the greater care in treating wounds from this cause.

Wyoming	...	...	...	...	...	...
Total	166	128	47	29	44	32
States reporting cases	29	25	18	15	15	12

Of the four cases of tetanus reported this year, three, or 75 per cent., were fatal as compared with 86 *per cent.* last year, 55 per cent. in 1911, 93 per cent. in 1910 and 84 per cent. in 1909.

TETANUS FROM INJURIES NOT CAUSED BY FIREWORKS

Besides the cases of lockjaw due directly to the use of fireworks, it is interesting to note also those occurring during the Fourth of July season which were due to penetrating wounds from other causes, such as nails, splinters, crushing injuries, etc. There was a slight reduction in these cases this year, thirty-two cases being reported as compared with forty-four cases last year. Tetanus germs, therefore, were apparently fully as prevalent if not more so this year than in previous years, which makes the marked reduction in recent years of cases from Fourth of July injuries all the more significant and gratifying.

DEATHS AND INJURIES NOT CAUSED BY TETANUS

Besides the three deaths due to tetanus, twenty-nine persons were killed by various forms of fireworks, making a total of thirty-two deaths, nine less than last year, twenty-five less than in 1911 and ninety-nine less than in 1910. This is the lowest number of deaths from such causes during the eleven years covered by the statistics of The Journal, and shows a most significant improvement over previous years. This year eight persons were killed outright by firearms, six by explosions of powder, bombs or torpedoes, one by a cannon and one of blood-poisoning following a slight injury by a large firecracker. The largest number killed by any one cause this year, however, were the thirteen persons, mostly little girls or small children, who were burned to death by fire from fireworks, two of these being reported as due to supposedly harmless "snapper matches." All accidents not due directly to the discharge or handling of fireworks or other means of noise production and display on or about the Fourth of July have been omitted. Table 6 shows a comparison of the causes of deaths aside from tetanus for the past nine years.

DISTRIBUTION OF INJURIES

In Table 7 a summary of all injuries, including tetanus, and of all causes, will be found arranged by states. Beneath the totals at the bottom are given, for comparison, the totals for the ten previous years and the grand totals for the eleven years. Table 8 permits the comparison by states of the total deaths and injuries for ten years. The number of casualties this year was 1,106, an increase of 116 over the total reported last year. In seventeen states the totals this year show an increase over last year, although in most instances the totals are less than two years ago. Pennsylvania had 491 casualties this year, an increase of 226 over last year and 49 more than in 1911. New York had 144 casualties, or 29 more than last year, but 93 less than in 1911. Missouri and Connecticut reported, respectively, 83 and 50 cases this year, the largest totals in those states since 1910. Illinois had only 47 cases as compared with 39 last year and with 218 in 1911. It should be noted that Illinois had 598 casualties in 1906 and 558 in 1908. The figures for the last two years are very small as compared with previous years for California, Illinois, Indiana, Iowa, Massachusetts, Michigan, Missouri, New Jersey, Ohio and Wisconsin. Marked reductions also are seen in New York. Pennsylvania last year had a marked reduction, but still leads in having the largest number of casualties. Of the 491 casualties in Pennsylvania, 340 were reported from Philadelphia.

TABLE 6.—CAUSES OF DEATHS NOT DUE TO TETANUS

Year.	Gunshot.	Fire from Fire-works.	Powder, Tor-pedoes, Etc.	Giant Crack-ers.	Cannon.	Other Causes.	Total
1905	37	23	6	5	7	17	95
1906	38	18	18	3	3	3	83
1907	20	31	13	13	3	22	102
1908	30	22	19	23	7	7	108
1909	17	37	16	7	7	6	90
1910	19	26	11	2	3	3	64
1911	11	12	9	2	5	8	47
1912	9	8	7	2	2	7	35
1913	8	13	6	..	1	1	29
Totals	189	190	105	57	38	74	653

NATURE OF NON-FATAL INJURIES

There were 1,131 non-fatal injuries this year, or 194 more than last year, but 415 less than in 1911. Two persons were totally blinded this year, twenty-two lost one eye each, ten lost legs, arms or hands, and forty-six lost one or more fingers. Although in the last two years there has been a marked reduction in the total number of non-fatal injuries, the totals of these more severe injuries are about the same as reported for the two previous years. The giant firecracker continues to hold the first place as a cause of lacerated wounds and is responsible for most of the losses of eyes, hands and fingers. This year 312 injuries were due to the giant firecracker. Firearms caused 169 accidents this year, including eight killed. Of the total number thus injured many were orderly persons who were struck by stray bullets from the reckless use of firearms by others, and two of these persons died. The use of cannon caused sixty-two injuries, including one killed. In the eleven years, a total of 41,280 people—the equivalent of over forty regiments—were killed or injured in the celebration of the Fourth of July!

TOTALS IN CHIEF CITIES

Table 9 shows the number reported killed and injured in our largest cities during each of the past seven years. The cities are arranged according to their population as given by the United States census in 1910. This table is

* Kind of fireworks causing six tetanus cases unknown. † Kind of fireworks causing 24 cases of tetanus unknown.

of particular interest, since the results in cities in which prohibitive or restrictive ordinances have been adopted can be seen. Prohibitive ordinances were enforced this year in Baltimore, Boston, Chicago, Cleveland, Detroit, Newark, Toledo, Trenton, Washington and elsewhere. Restrictive measures were used in New York, St. Louis, Pittsburgh, Buffalo and elsewhere. Philadelphia reported three deaths this year, Providence reported two, and one each was reported for Chicago, Boston, Baltimore, Pittsburgh and Detroit, making a total of only ten deaths in seven of our eighty-four largest cities, as compared with twelve killed last year, sixteen in 1911, forty-three in 1910 and eighty in 1909. For the last three years Philadelphia is the only large city having more than 100 injuries, having reported 340 this year, a marked increase over last year, when 127 were reported. Altogether 854 non-fatal injuries were reported for these large cities this year, as compared with 522 last year, 771 in 1911, 1,455 in 1910 and 2,935 in 1909. A slight increase over last year is seen in the records of most of these cities, although other cities, notably Chicago, Boston, Detroit and Milwaukee, have kept the returns down to last year's record or show even lower records. Of these eighty-four cities, twenty-five have a record of six or more injured, four more than last year, but twenty-two less than in 1910 and thirty-three less than in 1909. There were thirty-one of these cities which had a clean record this year, as compared with thirty last year, twenty-four in 1911, eighteen in 1910 and eleven in 1909. Probably the most marked reductions in the number of injured in the last few years have been in Chicago, Boston, Milwaukee and Newark. From Newark no casualties have been reported during the last three years, although there were 150 injured and one killed there in 1909. It is noteworthy that nearly two-thirds of all casualties this year were in fifty-three of these larger cities.

WHERE THE RESPONSIBILITY RESTS

As has been repeatedly stated in these annual reports, the responsibility for the great majority of Fourth of July injuries clearly rests with city governments, since the employment of death-dealing methods of celebration is subject to their regulation. It is clearly the duty of city authorities, therefore, to decide whether or not the maiming of hundreds, the agonizing deaths from lockjaw and the burning to death of little children by fire from fireworks are to be continued. If fifty-three of these larger cities would do as the other thirty-one have done there would be no casualties to report. Prohibitory ordinances are most effective and permanent, as shown by the results in Baltimore, Cleveland, Newark, Trenton, Chicago, Washington and elsewhere, and even restrictive ordinances, if they could be rigidly enforced, would have good results. But the enforcement of restrictive measures is difficult and requires constant vigilance on the part of the police. By the sound it is difficult to know whether an explosion is due to a firecracker 3 inches long or to one 5 inches long, or whether it is due to some other forbidden form of fireworks. Under the prohibitory ordinance, however, any explosion is recognized at once as a violation of the law. Again, the smaller firecrackers, sparklers and "snapper matches," which have been considered so harmless, caused the fires this year by which several girls or small children were burned to death.

RECENT PROGRESS

It was understood from the beginning that the obliteration of the sorrow and suffering needlessly caused during the annual celebration of the Fourth of July could be brought about only by a campaign of education vigorous enough to change a national custom which had endured for many years and which had its origin in a sincere display of patriotism. It was clear, however, that no patriotism was worthy the name which for its preservation required annually the sacrificing of hundreds and the mutilation of thousands of the youth of the land.

For several successive years The Journal had collected and published the statistics showing the results of the noisy, barbaric celebration of July 4, but apparently with very little effect. In spite of the efforts of The Journal and a few prominent newspapers, notably the Chicago *Tribune*, scarcely any attention was paid to the awful facts. In 1908, however, another table (Table 9) was added to The Journal's statistics, in which the number killed and injured in each of the eighty-four largest cities were shown. It was also shown that the responsibility for these casualties clearly rested with city governments. When the 1908 report was published, reprints were circulated far and wide among newspapers and other publications. The result has been most remarkable. Since that time not only has the press of the country generally taken up the cause, but also local, state and national organizations and societies have become interested. They have not only argued against the use of fireworks, but, more important, have also provided more rational and patriotic means of celebration. An unusually vigorous action has been taken by many city councils during the last few years in the adoption and enforcement of restrictive or prohibitive legislation, and each year these ordinances are growing more and more prohibitive. All of these forces have made most liberal use of THE JOURNAL'S statistics even though they have not always mentioned the source. Be that as it may, however, the result has been a marked reduction in the totals of casualties to a small fraction of what they were in previous years. The necessity of perseverence in this campaign for better methods of celebration is aptly shown by the record of Philadelphia. In spite of a most vigorous campaign which has been carried on during the last three years, that city still reports 340 casualties. A continuance of that campaign, however, will doubtless eventually give that city a better record. Reports received indicate that hundreds of smaller cities and towns, following the example of their larger sisters, are enforcing either restrictive or prohibitive measures. More of such measures should be adopted. More important still, there should be no relaxation in the enforcement of these ordinances such as is indicated by the increase of casualties this year over the number reported a year ago.

THE METHOD OF SUBSTITUTION

Better by far than the mere negative methods of restriction or prohibition, however, has been the extensive agitation by various societies for more sensible methods of celebration. Our national Independence Day must cease to be a day of destruction and become a day of recreation, joy and enlightenment. From many of our larger cities comes the news that instead of the ear-splitting din of former years, those cities this year were more quiet than on an average Sunday. In many cities special celebrations and parades have been tried. The display of flags, the music of bands, the children's parade, the witnessing of historic floats, the picnics, the trips to the parks and visiting of friends—these methods are surely a more fitting and patriotic way of celebrating the day than by the senseless din and destruction of former years. And the result of such methods is evident: the smallest number of lockjaw cases and other deaths reported in any year since THE JOURNAL began the collection of these statistics, fewer blinded eyes, fewer maimed bodies and an astonishing reduction in the number of injuries. There are still too many of these injuries, however, and this year in an increased number. The campaign must be continued until the nation's disgrace shall be entirely removed.

Reduction of Rent per Child.—Professor Broca of Paris has been instrumental in the founding of a Paris company which owns tenements to rent to families with children exclusively. With three children under the age of 16 the rent is reduced by 20 per cent. of the rent-rates current in the vicinity. A further reduction of nearly five dollars a year is made for each additional child under 13; of three dollars for each additional child between 13 and 14, and of about two dollars for children between 14 and 15. This plan puts a premium on large families, and seems to be working finely, the owners of the property being content with the 3 per cent. income when property around, not granting the reduction, brings in a larger revenue. Broca recently reported at the annual meeting of the society in question that the mortality in its tenements was only from 5.9 to 14.4 per thousand, while in similar quarters elsewhere it ranged from 18 to 25 per thousand. The official title of the organization is the Société des logements économiques pour familles nombreuses (Society to provide economical dwellings for large families). The tenements are of the type that rent usually for from $70 to $100 or $150 a year.

SATURDAY, AUGUST 30, 1913

THE FOURTH OF JULY IN 1913

Another Fourth of July has been celebrated; the returns are now all in; all cases of lockjaw that have developed from such injuries have been checked up; all fatalities have been investigated and the results have been tabulated. These results appear this week on another page.

DEATHS FROM FIREWORKS

The fatalities this year were not so numerous as last year, there being only thirty-two deaths from fireworks as compared with forty-one last year, 215 in 1909 and 466 in 1903. Only 3 of these deaths were due to tetanus as compared with 6 last year, 125 in 1909 and 406 in 1903. These marked reductions in fatalities and in the numbers of tetanus cases give the best evidence that the old-time barbarous celebration is about over.

TOTAL CASUALTIES

This year the total number of casualties including the non-fatal injuries was 1,163, as compared with only 988 last year, with 1,603 in 1911 and with 5,623 in 1908, when the highest number of casualties was reported. There was an increase, therefore, over the total for last year although a decrease below the totals reported in all previous years. It is interesting to note, however, that over 40 per cent. of all casualties were in Pennsylvania, which reported 491 injuries, including nine deaths. It is also interesting to note that of this total reported for Pennsylvania 340, or nearly 70 per cent., occurred in the city of Philadelphia. The citizens of Philadelphia, the birth-place of independence, always have been a demonstrative people, but unlike the country generally, they have failed to note that, hiding behind the fair name of patriotism, the celebration of Independence Day has degenerated into a disgraceful demonstration of lawlessness and disorder. The awakening appears near at hand, however, since during the last few years a vigorous campaign against the use of fireworks has been carried on by some of its most progressive citizens. The force of public opinion is already bringing results, since an ordinance prohibiting the use of fireworks was said to have been passed this year, although the increased number of injuries reported would indicate that little if any attempt was made to enforce it. A vigorous enforcement of that ordinance, therefore, would have done much to remove a disgrace not only from the fair city of Philadelphia, but also from the state and the entire nation. Outside of Pennsylvania there were only 672 casualties this year and only one other state, New York, reported more than one hundred injuries. In 1908 there were thirteen states reporting an average of nearly four hundred accidents each.

EVIDENCES OF PROGRESS

The returns this year show a decided progress, taking the country as a whole. A larger number of cities adopted prohibitory ordinances and many of the largest —Chicago as an example—reported the day as more quiet than the average Sunday. The people of these cities seem to have gladly welcomed their deliverance from the annual debauch of noise and destruction and have taken advantage of the parks, the bathing-beaches, the country or other places where the day could be enjoyed in quiet and in safety. After all, the chief objections to sane-Fourth ordinances came from those financially interested and from the hoodlum element which needed to be suppressed. In marked contrast with former years, there was in these cities little evidence of the use of fireworks, and the emergency hospitals and fire departments had almost nothing to do. On the other hand, flags, bunting, red-white-and-blue suits and parasols were everywhere in evidence. Most important, however, the enjoyment of the celebration was not marred by the usual aftermath of deaths, injuries and sorrow.

BEGINNING OF THE CHANGE

Eleven years have passed since The Journal began publishing annually reliable statistics concerning the awful cost in life and limb of the use of explosives in celebrating the Fourth of July. For six long years the reports seemed to have no effect in spite of the fact that pamphlets containing the statistics were widely circulated each year among civic officers and others. The appeals for saner methods of celebration seemed, with few exceptions, to fall on deaf ears. One of the most notable exceptions was the Chicago *Tribune,* which had for years carried on a propaganda of its own against the unnecessary toll of blood exacted by the "insane" Fourth. Finally in the report of 1908 The Journal began showing the casualties occurring in our largest cities. The figures revealed that a large majority of the deaths and injuries was clearly due to the lawlessness and disorder permitted in these cities. The corollary was also clear that the city governments were responsible for these deaths and injuries inasmuch as they could be prevented by the enforcement of restrictive or prohibitive ordinances. That report seemed to touch local pride; the press generally began publishing The Journal's statistics, naturally emphasizing the figures of the local city and state; civic and other organizations started campaigns for the suppression of fireworks and the encouragement of other methods; city councils and officers were stimulated to action, and since that year the progress for better methods of celebration has been remarkable.

SIGNIFICANCE OF THE CHANGE

The watchword of this country is individual liberty, and this was heralded to the world by the Declaration of Independence, the signing of which is celebrated, July 4. The manner in which this day has been celebrated is, therefore, a fair index of other tendencies in our national life. From the beginning the individual was left free to show his patriotism on July 4, just as he was given the largest freedom in religion, in business and in the other walks of life. Too much freedom led to abuses in the business world, even as too much liberty led to disorder and lawlessness in the celebration. The nation has had to learn that the greatest liberty to the greatest number demands that certain bounds be placed to the liberty of the individual. Only a few years ago there seemed to be many evils due to greed, political favoritism and special privilege, such as to threaten the very continuance of our government. Within the last few years, however, much publicity has been given to political and commercial trickery in high places and low, and as a result we see a decided trend toward better things.

The use of fireworks in the celebration of the nation's birthday undoubtedly began as a sincerely patriotic demonstration, and celebrators were left free to do as they chose. This liberty became more and more abused, however, until the celebration had degenerated into an annual orgy of lawlessness, rowdyism, noise, death and destruction. So fixed had become the habit of celebrating with fireworks, and so general had become the freedom of their use, that even babes were suffered to handle matches and fireworks so often deadly even to adults trained to use them. Worse and worse grew this pseudopatriotic orgy until it was annually demanding a toll of hundreds of children to be tortured by lockjaw, burned to death or otherwise slain, and thousands of others were blinded, maimed for life or otherwise injured. So settled was the nation in this annual debauch as to require the awful results to be given publicity time and time again through six long years before any appreciable check could be put to these crimes being committed annually in the name of patriotism! But as in other walks of life progressive citizens are successfully struggling for civic, state and national righteousness, so these forces are also making effective use of the statistics collected by THE JOURNAL and successfully striving to bring in a safer, more dignified and more truly patriotic celebration of the Fourth of July.

THE SEVENTEENTH INTERNATIONAL MEDICAL CONGRESS

In reviewing the Seventeenth International Medical Congress, one is first impressed with wonder at its stupendous size. No fewer than twenty-five separate governments sent official representatives, and between seven thousand and eight thousand members attended. Of these it is worthy of note that quite a considerable proportion were women, about eighty of them from English-speaking countries. This fact marks a significant change that has come over professional opinion since the time when the Congress last met in London, in 1881. On that occasion the Executive Committee decided to issue invitations to men only, with the result that "forty-three duly qualified medical women" entered a protest, drawing on themselves the following rebuke from the *Lancet:* "It is well to bear in mind that the Congress is a voluntary assemblage of medical men for a certain purpose, and that those who are not asked to join suffer no infringement of their rights."

Another comment by our estimable contemporary of that date which touched us more nearly, was the remark that almost the whole of the work in the pathological section was done by German, French and English members, "while the Americans, who were present in large numbers and took an active part in the work of other sections, furnished only a single short communication, so little is pathology even yet studied by American doctors." That stricture, if correct at that time, could certainly not be leveled against the American profession of to-day, for beside those who actually read papers or took part in the proceedings of the Sections of Pathology and Bacteriology—among whom are to be found Yandell Henderson, MacCallum, Warthin, Folin, H. Dakin, and Duval—were many physicians in the various sections whose pathologic work is well known.

A feature of great and encouraging interest in connection with the Congress was the large amount of space devoted by the leading daily newspapers, particularly the *Times* and the *Morning Post,* the *Daily Telegraph* and the *Standard,* to fairly accurate reports, not only of the social aspects and the principal addresses and burning topics, but even to the section work generally, at any rate in regard to such matters as could conceivably be deemed of public interest.

Particularly is it gratifying to note that at last the "conspiracy of silence," which has for so long prevailed over all attempts on the part of the profession to arouse the public mind to the venereal peril, has been overcome; and the important resolution passed by the Congress has been not only widely disseminated, but also commented on and generally approved. That resolution, after calling attention to the ravages caused by syphilis, urges the governments of all the nations represented at the Congress to institute confidential notification of syphilis to a sanitary authority, and to make systematic provision for the diagnosis and treatment of all cases of syphilis not otherwise provided for. It is also gratifying to learn on good authority that so far as the British government is concerned, it has acquiesced in the proposition, as was indeed foreshadowed in Lord Morley's speech at the government dinner to the Congress.

Yet another auspicious feature of the Congress was the greater extent of official recognition than has hitherto been accorded to such gatherings, in the dinner given by the government to the more eminent representatives of the Congress, at which Lord Morley, a high government official, speaking on behalf of the government, dwelt on the relations between the state and the medical profession, regarded as a potent factor in shaping public policy. He especially recognized the powerful influence that can and ought to be wielded by those attending the Congress toward the establishment of international amity and the suppression of those jealousies, fears and misunderstandings which imperil the peace and prosperity of nations.

While so many points mark progress in a proper estimation of the ideals of the medical profession, in one point at least there is a striking similarity between the conditions surrounding the two congresses. In 1881, as now, misguided persons were vigorously attempting to check the progress of medicine and science by restrictive or prohibitory legislation against experiments on living animals. Then, as now, men of practical knowledge pointed out clearly the actual benefits that had been derived from such experiments and indicated the deadly blow to all progress in medicine that the success of such attempts would entail. But how much greater, how much more overwhelming, is the mass of accumulated evidence that can be adduced to-day of the continuous stream of benefit to the human race—aye, even to animals—that has flowed, and is flowing, from animal experimentation. The cautionary remarks of Lord Morley at the government dinner, August 5, in which he referred to "the strong opinion prevailing in this country against experiments on living animals" was countered the next day, when Sir Ernest Schäfer, professor of physiology at Edinburgh University and president of the Section on Physiology, submitted the resolution which was there carried unanimously and subsequently endorsed at the closing meeting of the entire Congress:

> Experiments on living animals have proved of the utmost service to mankind in the past and are indispensable to its future progress, and accordingly, while deprecating the infliction of unnecessary pain, it is of opinion, alike in the interests of man and of animals, that every facility should be given to competent persons for the performance of such experiments under adequate supervision.

Not only this, but Harvey Cushing's brilliant address in surgery contained a well-reasoned and vividly illustrated argument and an emphatic protest against restrictive legislation which would seriously impede, if it did not entirely arrest, the progress of medical knowledge.

Finally, as to the hospitality accorded by our confrères of the British Empire to their guests and colleagues, it cannot be more suitably expressed than in the words used by the permanent commission in its report, "that it surpassed all expectations."

THE THERAPEUTIC RANGE OF SALVARSAN

It is not the intention now to discuss the therapeutic effects of Ehrlich's salvarsan and neosalvarsan in syphilis. Experience has shown that even under the most favorable conditions a *therapia magna sterilisans* cannot be secured uniformly in this disease by means of one or two injections of the remedy. Because high expectations were allowed to arise this partial failure of salvarsan to reach the utmost theoretic therapeutic ideals has had a tendency to create doubt in some persons as to the ultimate success of remedies built up experimentally in the way that salvarsan was produced. It will require years of experience and observation before the accurate range and limits of action of salvarsan and neosalvarsan in syphilis—the special indications, the limitations and the dangers—are established fully, and though they may fall short of what was hoped of them in syphilis, it always should be kept in mind that salvarsan does effect what must be accepted as a complete *therapia magna sterilisans* in certain human diseases. This is true of recurrent fever which is caused by a variety of spirochete. In a few hours after the injection of salvarsan the parasites disappear from the blood and crisis occurs followed by prompt recovery without recurrence. It is true also of frambesia or yaws, the tropical disease which resembles syphilis and is caused by a spirochete. Here a single injection is usually enough to cause a complete cure. In Surinam a hospital which usually cared for about three hundred patients with frambesia has been closed because of the rapid cure thus produced. In view of what actually is accomplished in the way of rapid and complete sterilization in these human infections there is no room for doubt and distrust of the possibilities of Ehrlich's method. And it does not seem likely that the therapeutic range of salvarsan is limited to syphilis, recurrent fever and frambesia. Numerous infectious diseases of different nature are said to be favorably influenced by its use (scarlet fever, small-pox, glanders, etc.), but no final conclusions can be based on the observations now at hand. Vincent's angina and other lesions due to oral spirochetes appear to be cured rapidly by salvarsan; in some cases local applications are sufficient. Aleppo boil and other diseases caused by organisms of the Leishmania group are also said to yield to salvarsan, and recently its use in amebic dysentery has been followed by strikingly favorable results (Hata,[1] Wadhams and Hill[2]); but here also further trials are necessary before any final judgment can be pronounced. There seems, then to be good reasons for the evidently increasing interest in what salvarsan and neosalvarsan may do in other diseases than syphilis, and if the therapeutic powers of these agents, the first finished product of the method used by Ehrlich in their discovery, are such as indicated, what shall we think of the further possibilities of the method itself?

THE ADMINISTRATION AND VALUE OF TETANUS ANTITOXIN

The growing practice of giving tetanus antitoxin for curative purposes by the intraspinal route receives increasing support from both the statistical and the experimental sides. Numerous observers have corroborated the findings of Meyer and Ransom and others that the tetanus toxin is absorbed from the infected wound along the nerves, and spreads into and through the spinal cord by direct extension. Toxin traveling along the nervous tissues is not readily neutralized by antitoxin in the blood, but antitoxin in the spinal fluid can meet the toxin in the nerve roots, and probably in the cord itself. A series of interesting studies by Permin[1] establishes these facts and adds some new ideas. He found that animals given large doses of tetanus antitoxin, and then injected into a muscle with three or four times the ordinary lethal dose, develop a local tetanus from the excess toxin which passes along the nerves and reaches the regional segment of the spinal cord without being neutralized. Intraspinal injection of antitoxin can prevent the passage of the toxin into the cord, and thus prevent the local tetanus. As others have done, Permin attributes the universal tonic spasm of general tetanus to multiple ascending spasms; but the convulsions he ascribes to irritation of the cerebrum, on the basis of experimental evidence obtained from decerebrated animals, and by intra-ocular injection of the toxin.

Antitoxin circulating in the blood after subcutaneous or intravenous injection has no demonstrable power to abstract tetanus toxin from the nervous tissue, and hence is powerless to prevent the action of this toxin. All that antitoxin can do is to saturate the toxin being formed in the site of infection before it has entered the nervous tissues, and thus prevent in some cases the absorption of the fatal dose. When present in the spinal canal the antitoxin can also neutralize the toxin which is being carried into the cord from the nerves, thus interrupting the poison before it reaches the place where its harmful action is developed. The prophylactic use of antitoxin depends on the binding of the toxin before any toxic quantity can be absorbed by the nervous tissues, and apparently is not associated with any considerable effect on the infection, in view of the reported cases in which a delayed tetanus has been observed after prophylactic use of antitoxin, presumably arising after all the injected antitoxin has been eliminated or neutralized. From the results of experimental studies, which are supported by such statistical evidence as is obtainable, the proper curative treatment in a case of actual tetanus should consist, in addition to radical cleansing and extirpation of the infected tissues and symptomatic sedative treatment, of the use of maximum quantities of tetanus antitoxin by both intraspinal and intravenous or subcutaneous routes—the former to block the passage of antitoxin from the nerves into the spinal cord, the latter so to saturate the blood and tissues with antitoxin that no more unbound toxin can enter the nerves. Patients so treated, who have not already a fatal quantity of toxin in their spinal cords, should recover in most if not all cases.

Statistics on the use in Denmark of tetanus antitoxin for curative purposes, largely by the simple subcutaneous route of administration, give encouraging results, which would probably be even better if the more vigorous methods were employed. Of 199 patients treated without antitoxin there were 21 per cent. of recoveries, while in 189 cases of quite similar incubation period in which antitoxin was given, 42.3 per cent. of the patients recovered. It is especially noteworthy that in the acute cases with an incubation period of less than ten days, which have a notoriously bad prognosis, ninety-two patients treated with antitoxin showed 27.2 per cent. of recoveries, while of ninety-four untreated patients only 5.3 per cent. recovered. If tetanus antitoxin has so much influence on mortality when it simply limits absorption from the wound, its effect will undoubtedly be much greater when it is also used to block the progress of the toxin already absorbed. In any case, the results of these and many other statistical studies leave no room for doubt that tetanus antitoxin is well worth while as a curative agent in developed cases. In its use as a prophylactic agent it must always be kept in mind that tetanus antitoxin does not remain long in the body; Ruediger[2] found that in guinea-pigs the protective influence is lost in three weeks, while Vaillard[3] states that in man it lasts but one or two weeks. Hence, in those cases in which complete removal of the infecting bacilli cannot be assured, a repetition of the injection is necessary. Cases of tetanus developing some weeks after prophylactic use of antitoxin are occasionally observed, and are undoubtedly due to neglect of this precaution.

WHAT IS A DIABETIC FOOD?

In another column we refer to the report on diabetic foods just issued by the Connecticut Agricultural Experiment Station. A discussion of these products naturally raises the question of "standards" and definitions, among the complicated meshes of which the unscrupulous may dodge just dietary demands even if they do not directly violate legal requirements. Naturally in this connection the question arises: What constitutes a "diabetic" food? Street and Mendel[1] point out that formerly an almost complete absence, or at least a marked reduction of carbohydrate was considered an essential characteristic of a true "diabetic" food. The advertising literature and labels of the manufacturers of food products sold specifically for diabetics almost without exception foster the belief that their preparations, if not entirely free from carbohydrate, are at any rate far lower in carbohydrate content than are ordinary foods of the same class. Some manufacturers have more recently taken advantage of the fact that certain practitioners of recognized authority sanction the temporary liberal use of starchy foods like oatmeal, potato or rice for the very special purpose of increasing carbohydrate tolerance, to intimate the desirability of having a certain amount of starch in diabetic foods. This is at best a poor excuse for a low-grade product; for there is in truth *no occasion to purchase special foods for the diabetic* if the problem at issue is merely one of an insignificant reduction in the carbohydrate intake. The mere curtailment of the amount of ordinary bread or cereal eaten will accomplish the same end without dietetic discomfort. Furthermore, the sole guide which the purchaser at present has in the selection of brands of diabetic foods is the occasional indication of their protein content. High protein is by no means necessarily coincident with low carbohydrate. A product may be two-thirds protein and still contain 30 per cent. of objectionable carbohydrate, whereas a competing product may have the non-protein deficit made up completely of desirable fat. The physician and the patient are to-day utterly at a loss to know the true carbohydrate content of most of the foods offered to them. In fact, so great has this uncertainty become, that many leading practitioners have abandoned the use of all special preparations, preferring greatly reduced allowances of staple products like ordinary bread, of which the carbohydrate content is known and subject only to slight variations.

[1] See Footnote 2, p. 689.

Street and Mendel insist that when a manufacturer offers a preparation as particularly suited for the use of diabetics, he removes that product from the category of ordinary foods and assumes new obligations to the consumer. The conditions surrounding its sale must necessarily be more exacting than for an ordinary food sold for ordinary purposes. They therefore propose that the following restrictions should apply to any preparation sold specifically as a "diabetic" food: 1. It should contain much less carbohydrate than is found in a normal food of the same class—certainly not over half as much. 2. The label should bear a correct statement of the percentages of protein, fat and carbohydrates present. 3. The amount of the different carbohydrates present should be declared on the label, that is, starch, sucrose, levulose, lactose, etc. 4. The processes of manufacture should be so standardized that uniformity of composition, within reasonable limits, will be maintained from year to year. 5. No statement should be placed on the label which would give the impression that any food in unlimited quantity is suitable for a diabetic patient. 6. In the advertisements of these foods emphasis should be put on the carbohydrate content rather than on the amount of protein present.

Unless something is accomplished in the near future in the way of following some or all of these suggestions, which seem both reasonable and logical, so-called diabetic foods must remain the object of uncertainty and suspicion and likewise fail, as a class, to appeal to discriminating physicians and well-advised patients as having any special therapeutic virtues. It is further particularly to the interest and advantage of the few producers of satisfactory products to protect themselves from the undeserved suspicion which their unscrupulous competitors force on them by a sort of legalized indifference and fraud.

Current Comment

COMMERCIALIZING THE INTERNATIONAL CONGRESS

The Seventeenth International Congress of Medicine has come and gone. As in all such cases, the congress itself and the exhibit held under its auspices will be used as advertising assets by firms and individuals who feel the need of something in that line. A letter (third-class mail) has been received addressed to "Monsieur le Docteur Directeur de The Journal of the American Medical Association." Enclosed were five sheets of thin paper each one of which bore the caption "17e Congrès international de Médecine, Section de Chirurgie, soussection d'Orthopédie." Each sheet—written in French—detailed the part that Monsieur Mencière of Reims played in the section of orthopedic surgery, describing as he did by means of wall charts (*planches murales*) his technic of "phéno-puncture" in "coxalgie douloureuse." Reference is also made to Mencière's "auto-modeleur à pression pneumatique," a piece of apparatus that the gentleman doubtless wants brought to the attention of the profession of medicine the world over. A thirst for publicity that inspires a physician to send broadcast to the medical journals of the world a synopsis of his remarks at a scientific meeting is so frank, so ingenuous, so childlike, that it disarms criticism.

Later: As we go to press we have received one more letter—still third-class mail—from Dr. Mencière. This informs us that on Aug. 6, 1913, at 3 o'clock, the gentleman described his operative technic by means of stereopticon slides (*avec projection*) before the Orthopedic section of the International Congress!

VERRUCA TRANSMISSION

A preliminary communication from Peru[1] has brought a suggestion that may solve the problem of verruca transmission. Dr. Townsend, who is engaged in the study of the Peruvian disease at Chosica, Peru, has come to the conclusion that a theory of tick transmission is at present untenable. The investigation of the distribution of various bloodsuckers occurring in the verruca zone must take account of the peculiar distribution of the disease, which is said to be confined to deep and narrow canyons, with much vegetation, heat, and little or no ventilation. It appears that the habits of *Phlebotomus* correspond minutely with the conditions of verruca occurrence and the verruca zones. The flies find ideal conditions for their breeding in the verruca canyons. They suck the blood of almost any warm-blooded animal and thus are quite independent of man. This accords with the verruca reservoir being located in the native fauna. Dr. Townsend announces his confident belief that the transmission experiments, now about to be initiated with these gnats on laboratory animals, will demonstrate their agency in the transmission of the disease. We expect shortly to publish a report by Townsend of these experiments.

A REPORT ON DIABETIC FOODS

The subject of diabetic foods is one which THE JOURNAL has discussed at various times in the past in the hope not only of furnishing reliable guidance to those physicians who are interested in the management of diabetes, but also of awakening a much needed reform in the character of the manufactured products sold as diabetic foods. The subject is of vital importance to diabetics and to physicians who want to treat these unfortunates in a scientific manner. A while ago we published a brief preliminary survey of the diabetic foods on sale in the United States.[1] The detailed report, prepared by J. P. Street, chemist of the Connecticut Agricultural Experiment Station, and Lafayette B. Mendel of Yale University, has now appeared.[2] We do not know of any work done on this subject which compares in thoroughness and usefulness with this detailed report from the Connecticut Agricultural Experiment Station. Every physician who is interested in the subject of flours and foods having, or supposed to have, a low carbohydrate content, and certainly every physician who has a diabetic patient, should send for it.

CORPUS LUTEUM AND MAMMARY GLAND

It has been well established that the mammary glands may begin to hypertrophy during pregnancy after complete division of all the possible nervous paths between them and the tissues more directly involved in the developmental changes, namely, the ovaries and uterus. Starling and Lane-Claypon demonstrated that a somewhat similar mammary hypertrophy may be found in virgin rabbits after the injection of watery extracts made from fetal rabbits. This observation forms the basis for the current "hormone" theory regarding the initiation of growth in the mammary glands during pregnancy, for it points clearly to the fact that a chemical substance—a hormone—produced in the fetus and transmitted through the placenta to the maternal blood-stream may become an essential factor in the initiation of mammary development before lactation. This fetal hormone is not the only factor involved in the growth of the mammary gland. Bouin and Ancel[3] have furnished evidence that the corpus luteum—the tissue produced when a follicle of the ovary is ruptured and an ovum discharged—may also be concerned in the development of the mammary gland and lead to its hypertrophy quite independently of the presence of actual products of conception in the uterus. The rupture of ripe follicles can often be induced by purely mechanical or artificial means. The French investigators have shown that this is ordinarily followed by the formation of corpora lutea and also by a growth of the mammary glands. Recent experiments of O'Donoghue[4] in the main confirm this interesting finding of Bouin and Ancel. They further provide a valuable piece of negative evidence. According to O'Donoghue, the rupture of the follicles is not invariably attended by the formation of corpora lutea. When the formation duly occurs there is also a growth of the mammary glands. In rabbits, the amount of growth in fourteen or fifteen days was about equal to that of the normal pregnant female of twelve days. On the other hand, if the follicular rupture is not succeeded by the formation of corpora lutea, then no growth of the glands ensues even though the operative procedures have been precisely the same in the two cases. These facts serve to lend new emphasis to the dependence of such physiologic responses as mammary development on other than purely nervous relations. They add to the coming significance of hormone activities in the interdependence of various parts of the organism.

ENCOURAGEMENT

The attempt of a philanthropic gentleman in the coal business to enrich—for a consideration—the armamentarium of physicians is discussed briefly in the Propaganda for Reform department. The thing itself is but a trivial episode in contemporaneous quackery, yet the matter has been one of special encouragement. Had this same scheme been worked six or eight years ago, it is doubtful whether half a dozen physicians would have taken the trouble to bring the matter to THE JOURNAL'S attention. To-day, apparently as a matter of course, more than half a hundred wide-awake members of the profession, in one state, immediately bring this attempt to exploit the doctor to the notice of their own journal. Such spontaneity of action is decidedly encouraging.

HAPGOOD RUNS TRUE TO FORM

The aforetime readers of *Harper's Weekly*—the oldest illustrated weekly newspaper in the country—will hardly recognize it under its new ownership and editorship. The change is radical; everything is new but the name: typography, make-up, arrangement—all are different, and better. But the greatest difference is in the character of its contents—and of course this might have been expected with Norman Hapgood as editor. *Harper's Weekly* is no longer mainly political; it is so only incidentally. As its subtitle has already had it, it is indeed again "a journal of civilization"; or probably it would be better to say *"for* civilization." This comment, however, is mainly to call attention to, and to quote from, one item in the initial number under Mr. Hapgood's editorship. After referring to the many letters that the editor had received asking that "both sides" be given in the vivisection controversy, and stating that if a course hostile to the antivivisection crusade were pursued the writers would not subscribe, *Harper's Weekly* says:

---

[1] Street, J. P.: Diabetic Foods Offered for Sale in the United States, THE JOURNAL A. M. A., June 28, 1913, p. 2037.

[2] Street, J. P., with the assistance of Mendel, L. B.: Diabetic Foods, Report Conn. Agric. Exper. Sta., Food Products and Drugs, 1913, Part 1, Section 1. This report is available free to those who apply to the Connecticut Agricultural Experiment Station, New Haven, Conn.

[3] Bouin, P., and Ancel, P.: Sur la fonction du corps jaune, Compt. rend. Soc. de biol., 1909, lxvi, 605, 689.

[4] O'Donoghue, C. H.: The Artificial Production of Corpora Lutea and Their Relation to the Mammary Gland, Jour. Physiol., 1912, xlvi, 6.

> We have no intention of giving both sides. On the contrary, the support of the cause of scientific medical progress will be one of the things to which we shall be energetically devoted. We shall no more give both sides of the argument on experiment than we shall give both sides of the question of whether the household fly shall be encouraged in the dining-room, or sewers emptied into the city reservoir, or swamps kept for the breeding of mosquitoes, or small-pox patients permitted to ride on the street-cars. We shall be extremely bigoted on the subject, and shall hope that the day will soon come when cancer will be added to the great diseases that have yielded to investigation.

We congratulate Mr. Hapgood on the fact that he has the courage of his convictions and is not afraid to express them. Also, we congratulate him on the various good things he has introduced into this *new* journal published under an old name.

Medical News

ALABAMA

Hospital Cornerstone Laid.—The cornerstone to the addition to the Hillman Hospital, Birmingham, was laid with Masonic rites, August 26.

Hospital Addition Completed.—The addition to the Mobile City Hospital which will accommodate eighty patients, is nearly completed. The building is two hundred feet long and connected with the present hospital building by a corridor. On the ground floor an out-patient department and x-ray, clinical and anatomical laboratories are provided.

Personal.—Dr. Andrew H. Ryan, formerly professor of physiology and pharmacy in Washington University, St. Louis, and more recently assistant professor of physiology and pharmacy in the University of Pittsburgh, has accepted the professorship of physiology in the School of Medicine in the University of Alabama, Mobile. Dr. Howard H. Bell has been appointed full-time assistant in the department of pathology and bacteriology in the university and Dr. Jesse P. Chapman, assistant instructor in orthopedic surgery in the institution.

CALIFORNIA

Personal.—Dr. L. L. Stanley has succeeded Dr. H. N. Kierulff as physician at the San Quentin State Prison and Dr. Francis Stolle, San Francisco, has been appointed assistant physician.——Dr. Charles T. Palmer, assistant health commissioner of Los Angeles, has resigned.

Hospital News.—Plans are being prepared for a new building to be erected for the French Hospital Association, College and Castellar streets, Los Angeles. The building is to be of reinforced concrete construction and will cost about $50,000. ——The supervisors of Marion County have authorized the construction of a county hospital building to cost $40,000 and to accommodate seventy-five patients. It will be of fireproof construction and will be located about four miles from San Rafael.——The contract has been signed for the construction of a hospital building for the Sisters of Mercy at Oxnard. The building will be 150 x 42 feet, of brick construction, two stories and a basement in height and will cost $42,000.——Plans are being prepared for a group of buildings to be erected on Marengo Avenue, Pasadena, for the Marengo Avenue Hospital. The main building will be a four-story reinforced concrete structure.

GEORGIA

Appropriation for Medical Department.—The legislature of Georgia has decided to give the medical department of the university, Augusta, an appropriation of $30,000 a year for the next two years, and the governor signed the bill providing for this, August 20.

ILLINOIS

Advisory Committee Appointed.—President McCormick of the Cook County Board of Commissioners has appointed a committee of experts to visit the tuberculosis institutions in Cook County and report as to conditions found and suggest means of improvement. The committee consists of Dr. Theodore B. Sachs, chairman; Drs. Stephen R. Pietrowicz and Ethan A. Gray and Mr. James Minnick.

Civil Service Examination.—The State Civil Service Commission announces that examinations will be held September 6 at various points in the state for general physician, class A, grade II, salary of $75 to $125 a month and maintenance, open to men and women between the ages of twenty-one to fifty. This examination is open to non-residents of Illinois; and for hydrotherapist at the Kankakee State Hospital, class B, grade II, salary of $60 to $75, open to persons over twenty-one years of age and local residence is waived. Application for above examinations and requests for information should be addressed to W. R. Robinson, chief examiner, State Civil Service Commission, Springfield.

Personal.—Dr. H. Lewis Pintler, Peoria, who has been critically ill in Chicago, is reported to be improving.——Dr. Emil Haass, Frankfort, celebrated his eighty-sixth birthday anniversary August 5.——Drs. J. Sheldon Clark, Freeport, and Carroll B. Welton, Peoria, sailed for Europe, August 9.——Dr. Joseph Cooperstein, Chicago, has been appointed assistant physician at the Chester State Hospital, vice Dr. William Hersio. ——Dr. T. McLain, assistant physician at the Peoria State Hospital, has been transferred to the Jacksonville State Hospital, vice Dr. Walter Treadway, resigned, to enter the U. S. P. H. Service.——Dr. E. W. Fell, Jacksonville, has been appointed assistant physician at the Elgin State Hospital, vice Dr. E. J. Kelloch, resigned.——Dr. J. S. Thrailkill, Bethalto, was seriously injured when his automobile went over a thirty-foot embankment in Alton, August 15. One leg was fractured and he sustained serious cuts and bruises.——Dr. Joseph M. Campbell, Marissa, has been appointed superintendent of the Watertown State Hospital.——Dr. J. L. Aleshire, Plainsville, was operated on for appendicitis recently and is reported to be doing well.——Dr. Russell V. Thomas has been appointed local surgeon for the Illinois Central Railroad at Manteno vice Dr. Zephrita Rouleau, deceased.——Dr. Andrew M. Harvey has moved his residence to La Grange, Ill.——Dr. and Mrs. Herman L. Kretschmer have sailed for Europe.

Chicago

Baby-Saving Campaign.—The Civic Federation of Chicago, in the hope of reducing the infant mortality rate in the city, has commenced a campaign of education by means of posters, urging mothers in the crowded wards of the city to "Keep Your Baby Well," and giving the addresses of the nearest Infant Welfare Society stations and the Elizabeth McCormick Baby Association at which free advice and care is given to all mothers.

INDIANA

Bequest to Hospital.—The Methodist Episcopal Hospital, Indianapolis, which at the present time is erecting its second annex, will benefit to the extent of two hundred acres of valuable land from the will of Simeon Smith, who recently died, near Bloomfield.

New Hospital.—The Elkhart General Hospital, erected at a cost of $80,000, was opened to the public, July 26-27, with a reception given by the board of directors and the officers of the Elkhart Training School for Nurses. During the two days five thousand residents of Elkhart and vicinity visited the school.

Hospital Improvements.—The Long State Hospital and the two units of the new Indianapolis city hospital will be ready for occupancy this fall. These buildings in connection with the annex of the Methodist Episcopal Hospital and the new St. Vincent Hospital will give Indianapolis ample hospital facilities for several years.

County Sanatoriums.—A hospital for the treatment of tuberculosis will be erected in South Bend, Indiana, at a maximum cost of $50,000. Thirty acres of land necessary to complete it have been condemned by the county commissioners and a board of four members, two of which must be physicians, will be appointed to supervise its erection.

Receiver Named for Sanatorium.—On application of the Pittman and Myers Company, manufacturing pharmacists of Indianapolis, Judge Brill has appointed a receiver for the Rockwood Tuberculosis Sanatorium, located six miles east of Danville; under bond of $25,000, with instructions to operate the institution until the property can be sold to an advantage.

IOWA

New Officers.—Fort Madison Clinical Society; president, Dr. J. R. Walker; secretary, Dr. J. G. Rea.

Personal.—Dr. S. C. Dunkle, Glidden, was operated on in Rochester, Minn., August 13, and is reported to be doing well. ——Dr. C. B. Burk, Atlantic, is said to be seriously ill with typhoid in Mercy Hospital, Council Bluffs.——Dr. Henry G. Langworthy, Dubuque, was operated on recently at Mercy Hospital for appendicitis.——Dr. O. W. Lowrey, Des Moines, was seriously injured by the overturning of an automobile near Oskaloosa, recently.——Dr. H. H. Nichols, Marshalltown, who underwent a serious operation at St. Thomas Hospital, recently, is reported to be convalescent.

KANSAS

Advisory Committee for State Board Named.—B. L. Thompson, a butcher, of Harrington, James Campbell, a candy maker of Salina, and W. F. Jackson, Fort Scott, of the Bourbon County retailers, have been appointed advisory members of the State Board of Health to represent the merchants of the State and to aid the board especially as regards pure food matters.

KENTUCKY

Bacteriologic Exhibit for County Fair.—The assistant state bacteriologist is preparing a bacteriologic traveling case of exhibits of local conditions for the county fairs of the state. The exhibit is for educational purposes only and is accompanied by similar cases prepared by the Experimental Station.

MARYLAND

Baltimore

Personal.—Drs. J. L. Hooper and Robert Hoffmann have sailed for Europe.——Dr. A. L. Fehsenfeld has been appointed medical examiner of schools, vice Dr. I. F. Page.

Purification of Drinking Water.—The health authorities are using three thousand pounds of hypochlorite of lime daily, with a view of purifying the drinking water of the city and limiting the prevalence of typhoid fever. A report shows that 99 per cent. of the bacteria in the water last year were killed by the use of hypochlorite of lime.

NEW YORK

Large Contributions to Tuberculosis Fight.—It has been announced by the State Charities Aid Association that gifts to aid the campaign against tuberculosis totaled $630,500, the largest contribution having been made by the late Mrs. Elizabeth M. Newton of Fredonia, N. Y., who bequeathed $150,000 for the purpose of founding a hospital for consumptives in Chautauqua County.

Violent Deaths in June.—There were 473 violent deaths in the state during June. Of these, 146 were from drowning, 145 died in railroad accidents, 116 were suicides, 44 were murdered, 12 died by electric shock, 7 from sunstroke and 3 were killed by lightning. June had 10,865 deaths, an average of 362 daily; of the uncommon or infrequent causes of death, 9 were tetanus and 6 from poliomyelitis.

Cottage Settlement for Consumptives.—Mrs. Thomas F. Ryan has purchased a 100-acre farm near Sloatsburg, Rockland County, where she proposes to establish a colony for the consumptives of that county. The site was recommended by Dr. Herman Biggs, and the buildings will be begun at once. The first object of the home is to provide for the consumptives of Rockland County but it is understood that if those from elsewhere knock for admission they will not be refused.

The State Health Department and Sex Hygiene.—In connection with the new work of the State Health Department in teaching sex hygiene circulars have been prepared and are being circulated entitled "Sexual Hygiene for Young Women," "Sexual Hygiene for Young Men" and "Suggestions to Persons Having Venereal Diseases." The work is carried on principally by lectures and exhibits. It is proposed to reach girls working in industrial establishments. In view of the increasing prevalence of cancer in this state and the fact that cancer so often attacks one or more of the sexual organs of the female, it is proposed to include in the educational campaign some lectures dwelling on the early diagnosis, means of prevention and necessity for early skilled treatment of cancer. In this phase of the subject the State Health Department will have the cooperation of the New York State Cancer Laboratory.

New York City

Personal.—Dr. and Mrs. Henry W. Mooney and Dr. and Mrs. C. E. Scofield, Brooklyn, have sailed for Europe.——Dr. Henry Mann Silver is rapidly convalescing from an operation for the removal of gall-stones, recently performed in Roosevelt Hospital.

Lower Death-Rate Among Babies.—For the week ended August 16 there were only 170 deaths of infants under one year, as compared with 194 for the corresponding week of 1912. The city has now passed the middle of August with a record of 309 fewer deaths than had occurred up to the same time last year.

To and From Europe.—*Among those who have returned from* Europe recently are Dr. and Mrs. Hermann M. Biggs, Dr. and Mrs. George E. Brewer, Dr. and Mrs. Howard C. Taylor, Dr. Richard H. Gibbons, Dr. Charles Ogilvy, Dr. Philip Van Ingen, Dr. and Mrs. Philip Embury, Dr. and Mrs. Fred H. Albee and Dr. H. G. Anderson. Among those who have sailed for Europe recently are Dr. and Mrs. S. Wells Churchill, Dr. H. Bayard Clark and Dr. William M. Ford.

Court Upholds Vaccination Law.—In the case of Hagbard Ekerold who refused to keep his child in school unless the board of education assured him that the child would not be subjected to vaccination, Judge Rosalsky of the general sessions court upheld a fine of $5 which had been imposed on the defendant by a police court and suggested that the case be carried to the higher courts in order to make a test case as to whether the action of the board of education on the subject of vaccination was in accord with the law.

Infant Deaths Increase in Three Boroughs.—Thus far for the year 1913 there have been 268 fewer deaths among babies than during the same period of 1912. During the week ending July 26 there were 53 fewer deaths among infants than during the corresponding week of 1912, though there was a considerable increase in the death rate in three boroughs, Richmond, Brooklyn and Manhattan. Thus far this year there have been 131 deaths from diarrheal diseases as against 164 for last year.

Court Decides Against Smoke Ordinance.—In the case of the Board of Health against the New York Edison Company the court has decided that the Health Department has enforced the ordinance against the smoke nuisance "unreasonably and unconstitutionally." There is a widespread sentiment that this decision is unwise and that if the smoke nuisance cannot be regulated by ordinance it will have to be controlled by legislation. It is hoped that an appeal in the case in question will result in a reversal of the decision.

Rules Sent to Milk Dealers.—The Health Department has sent to all stores where dipped milk is sold a set of rules which require that milk shall not be sold or stored in rooms used for cooking or other domestic purposes, or in any room where there is a lavatory. Milk must be kept at a temperature of 50 degrees or lower at all times. Such rooms must be clean, well lighted and screened. Dry dusting or sweeping in a room where milk is sold is prohibited. Only such persons shall be employed as are free from diseases which may be transmitted.

New Health Regulations.—There will be two important changes in the old system of dealing with cases of diphtheria, scarlet fever and measles. Insusceptible persons will *not* be excluded from school while a case of infectious disease exists at home, provided isolation is properly carried out. Quarantine in cases of measles will be terminated five days after the appearance of the rash, if such a course is warranted by the clinical condition. Periodic visitations will be made by nurses, and, if the regulations are disobeyed, the patients may be removed to a hospital.

Summer Hospital Will Keep Open All Year.—At a meeting of the board of trustees of St. John's Guild recently, it was decided to keep the Sea Side Hospital at New Dorp, S. I., open during the entire year instead of during the summer months only. The new buildings and equipment have made it possible to care for convalescent mothers who have been discharged from city hospitals and also to continue the treatment of orthopedic cases through the winter. Thus far this season 1.624 patients have been admitted to the hospital with an average stay per patient of 9.7 days.

Bequests.—The will of Mrs. Julia Lorillard Butterfield, the widow of General Daniel Butterfield, leaves about $350.000 to charitable and educational purposes of which the Association for the Relief of Respectable Aged Indigent Females receives $20,000 and the Association for the Aid of Crippled Children, $10,000. A bequest of $40.000 is made for the erection of a hospital in Cold Springs, N. Y., $40,000 is left for its equipment and $100.000 for its maintenance.——The will of Henry Korn gives $500 each to the Lebanon Hospital. Mount Sinai Hospital. Beth Israel Hospital and Montefiore Home.

To Help Expectant Mothers.—Through the generosity of Mrs. Robert H. Sayre five lots on the shore of Oak Beach. L. I., have been leased where cottages will be erected which will furnish single rooms to 100 expectant mothers. The funds for the buildings have been donated by a woman who has requested that her name be withheld from the public at present. It is proposed to take the expectant mothers for a month and to give them good food. rest and instruction in how to care for their babies. The work done in this direction by the milk stations has reduced the infant death rate to such an extent that it is believed that such an institution will be a great factor in lowering infant mortality.

New Children's Court.—The cornerstone of a new court house for children was laid on August 9 when it was explained that in this building the suggestion of a court of law would be eliminated as far as possible. Only those directly interested in the cases will be permitted in the room. Boy and girl delinquents will be brought to the room through a separate entrance and care will be taken to segregate them. The court is to be regarded as an experiment station where delinquent children will fall into the hands of those who understand them. On the cornerstone is inscribed "For every child let truth spring from earth and justice and mercy look down from Heaven." Proper provision will be made for the examination and diagnosis of the cases, and after diagnosis, for proper treatment through probation, thorough investigation of home conditions, and when necessary for commitment.

NORTH CAROLINA

Resigned to Help Hospital.—In order to disabuse the public of the idea that the Mission Hospital. Asheville, is a close corporation rather than a public institution, the members of the staff and adjunct staff have resigned. The campaign to raise $100,000 for a new building for the hospital will now be carried on actively.

Personal.—Dr. J. V. McGougan, Fayetteville, entertained the members of the Hoke-Cumberland County Medical Society, their families and invited guests, in number more than one hundred, with an old fashioned barbecue at his country home "Skiboo Place," August 11.——Dr. C. B. Woodley, Kinston, has been successful in his case in the Superior Court which involved the right of the telephone company to discontinue telephone service of a physician without his consent.

PENNSYLVANIA

Insane Hospitals Must File Reports.—The attorney general's department has handed down an opinion that no payments of appropriations can be made to the state insane hospitals unless they file quarterly reports.

To Build Hospital Group.—A group of six buildings of one, two and three stories in height, to cover an area of 150 by 558 feet, in Westmoreland County, will be built for the Westmoreland Hospital for the Insane.

Typhoid Traced to Milk.—The State Department of Health has completed investigations at Chester and confirmed the opinion of the local health authorities that the outbreak of typhoid fever was due to infected milk.

Hospital News.—The erection of the proposed St. Mary's Hospital, South Scranton, has been postponed on account of the bids submitted being in excess of the sum planned and secured for the work.——Chester Hospital has secured a new motor ambulance, the $4,000 for the purchase of which was secured by public subscription.

Personal.—Dr. J. C. Price, Scranton, has been appointed chief medical inspector of the newly instituted department of labor and industry.——Drs. E. E. Lamb, H. E. Helling and C. M. Iseman have been appointed directors of the Ellwood City Hospital Association.——Dr. John T. Eckert, Allentown, was seriously injured by the overturning of his automobile, August 5.

Hospital Notes.—The contract has been awarded for a two-story addition to the Hospital of the Good Shepherd, Rosemont.——A free dispensary has been opened in connection with the Crozer Hospital, Chester.——The Coatesville Hospital has arranged a department for sick babies which will be opened by the first of October.——Reading has opened its isolation hospital for small-pox at Avon, July 21.

Philadelphia

Personal.—Dr. W. H. Blakesley has been appointed medical inspector in the State Department of Labor and Industry.——Dr. Milton B. Hartzell has succeeded Dr. J. F. Schamberg, resigned, as assistant diagnostician and consultant to the Municipal Board of Health.

Increase Medical Course.—The Jefferson and Medico-Chirurgical Colleges announced on August 19, that no person will hereafter be admitted to the regular medical courses who has not spent a year in obtaining a premedical education, to consist chiefly of collegiate biology, chemistry, physics and German.

City Eye Dispensary Established.—A branch of the eye dispensary which has been maintained in the City Hall by the Department of Health and Charities for several years, will be established at the Southwark School and will be in operation at the end of the summer vacation. Dr. William J. Ryan will be in charge of the dispensary.

Impure Food in Storage Plants.—The State Dairy and Food Commission, making an investigation of all cold-storage establishments preparatory to the enforcement of the Gans bill which went into effect August 14, found decomposed meat and other food products in great quantities. In one of the refrigerating plants approximately 1,000 pounds of decomposed meat was ordered destroyed.

Charitable Bequests.—The will of the late Mrs. Anna F. Francine makes provisional bequests of one-third of her estate which is valued at $130,000 to the University of Pennsylvania Hospital, and the other two-thirds to the trustees of the Pennsylvania Epileptic Hospital and Colony Farm in Chester County.——The will of the late Henry Freedman gives $500 to the Jewish Hospital.

Notice to Milk Dealers for Next Summer.—The rule that all milk and cream sold in this city must be pasteurized by a process approved by the Board of Health, in addition to meeting the requirements imposed on the milk traffic, goes into effect July 1, next. The reason for the delay in enforcing the rule is that a drastic change will be made in the handling of the milk under the new regulation and dealers must install equipment to carry out this rule.

To Prevent Typhoid.—On August 22, Chief Vogelson, of the Bureau of Health, sent a circular letter to factory owners, urging their cooperation in effectually and promptly stopping pollution of filtered water through raw water pipe connections on their premises, for fire protection or manufacturing purposes, as much of the increase in typhoid fever is believed to be the result of contamination of city water mains by such private raw water piping systems.

Legality of Vivisection to Be Settled.—In the fall, an effort will be made to settle finally the legality of vivisection, when six physicians of the University of Pennsylvania will be arraigned before the grand jury. The Women's Pennsylvania Society for the Prevention of Cruelty to Animals is supporting the prosecution. The accused physicians ars Drs. Allen J. Smith, Edward T. Reichert, Alonzo E. Taylor, Joshua E. Sweet, Richard M. Pierce and Alfred M. Richards.

Summer Outings to Red Bank.—The two boats, The John F. Smith and the Elizabeth M. Smith, named after the donors of the free hospital and playground at Red Bank, N. J., make nine trips daily between that place and Philadelphia and carry about 600 women and children. These boats rechristened by the children, "The Johnny Boat" and "The Lizzie Boat," are rounding out thirty-six years of service and in that time have carried 3,456,134 persons from the tenements to Red Bank. There are all sorts of amusements for the children in the playground and luncheon is served about 11. Last summer 23,920 quarts of soup, 6,036 cups of tea, 3,566 quarts of milk and 98 barrels of crackers were dispensed. For babies too small to go into the bathing pools, there is a separate bathing house with twenty-two baby tubs and there are also tubs for the mothers. The hospital building is three stories high and accommodates eighty mothers and babies.

Infant Mortality Increasing.—Despite the numerous public and private baby saving enterprises in operation during the summer, figures compiled by the Department of Health show a decided increase in infant mortality for the first six months of this year as compared with the same period in 1912. The following table shows the increase over last year:

Age at Death	1912	1913
Under 1 year	1,904	2,203
1 to 2 years	430	518
2 to 5 years	451	523
5 to 10 years	259	305
	3,044	3,549

The general increase in the rate of mortality under 10 years of age is ascribed by Dr. Neff to the epidemic of measles that was prevalent in the city during the winter. The department is maintaining or helping to maintain six agencies throughout the city whose sole purpose is saving the baby. These include the Baby Hospital on the Race street pier, the instruction camp on the Chestnut street pier, Children's Hospital at Blockley, the maintenance of eight municipal nurses for private visiting, the permanent baby show at City Hall and interest in the Babies' Hospital at Wynnefield.

Care of Milk Supply of City.—Director Neff of the Bureau of Health and Charities has issued a bulletin warning milk consumers to protect themselves against inferior and unclean milk. Some of the directions contained in the bulletin follow:

> Cleanliness and cold are necessary to keep milk wholesome at home, as well as at the dealer's. Keep milk in the milk bottle, or container, covered, until wanted, and then pour out only as much as will be used at the time. Wipe the mouth of the bottle with a clean towel before removing the cap. Rinse the cap in running water before replacing it. If the cap is broken, place an inverted tumbler over the mouth of the bottle.
>
> All dishes, containers and utensils used for milk should be kept perfectly clean, first by being rinsed as soon as emptied, or directly after being used, with cold water, and then being boiled in clean water and set away, unwiped, bottom up, to dry. They are kept in much better condition this way than when cleaned in dish water and wiped with the ordinary dish towel. Do not use milk jars for any other purpose than holding milk.
>
> Keep milk in a separate compartment of the refrigerator. Milk absorbs unpleasant odors, as well as germs. Refrigerators should be kept clean and sweet; the outlet for melted ice should be properly trapped and the trap kept clean. Scald the food compartment of the refrigerator every week with a washing soda solution.

The following table shows the work of the health department for the first six months of the current year in looking after the city's milk supply.

Number of milk inspections		47,131
Number of quarts inspected		1,937,454
Number of quarts condemned and destroyed:		
On the street	1,692	
On the platform	11,241	12,933
Number of samples tested:		
Bacteriologically		2,095
Microscopically		1,061
Chemically		66
Milk licenses revoked		5
Cows inspected		3,299
Cows condemned		12
Farms and stables inspected		267
Pasteurizing plants inspected		91

TENNESSEE

Malaria in Memphis.—The superintendent of the Memphis City Hospital reports that from Sept. 1, 1912, to June 30, 1913, 393 cases of malaria were received in that institution. Of these 146 were white males, 37 white females, 174 colored males and 33 colored females. Of the first class, 100 were reported cured, 41 improved and 4 unimproved with 1 death; of the second class, 26 were cured and 10 improved with 1 death; of colored males, 143 were cured, 29 were improved, 1 unimproved and 4 died, and of colored females, 24 were cured and 9 improved.

VIRGINIA

New Officers.—Piedmont Medical Society at Fredericksburg: president, Dr. Harry L. Baptist, Ivy Depot; secretary, Dr. F. G. Scott, Jr., Orange.——Old Dominion Medical and Surgical Society at Petersburg, August 12: president, Dr. Thomas J. Fawcett, Lynchburg; secretary, Dr. W. A. Crowder, Petersburg.

Personal.—Dr. F. P. Dickinson, Fredericksburg, was thrown from his buggy in a collision with another vehicle, recently, fracturing his clavicle.——Dr. H. A. Warren, Suffolk, was operated on recently at Lakeview Hospital.——Dr. A. G. Crockett, Wythesville, was seriously injured in a runaway accident at Fort Chiswell, recently.

City to Build Hospital.—A resolution was introduced recently in the board of aldermen of Richmond, directing the council committee on public buildings, properties and utilities to examine into the feasibility of erecting a new and modern city hospital on the State Home property. The present city hospital is said to be inadequate to the needs of the municipality.

GENERAL

Mississippi Valley Medical Association Meeting.—The thirty-ninth annual meeting of the Mississippi Valley Medical Association will be held in New Orleans, October 23-25, under the presidency of Dr. Albert E. Sterne, Indianapolis.

Electrotherapeutists to Meet.—The twenty-third annual meeting of the American Electrotherapeutic Association will be held at the Engineering Society's Building, 29 West Thirty-Ninth Street, New York City, September 2-4, under the presidency of Dr. F. Howard Humphris, London, England.

Ophthalmologic Congress.—The Oxford Ophthalmologic Congress was held at Keble College, Oxford, July 17-18. Addresses were delivered by Prof. Emil von Grosz, Dr. John O. McReynolds, Dallas, Tex., Dr. J. Igersheimer, Lieutenant Colonel R. H. Elliot, I. M. S., Dr. J. Mawas, Dr. Franz Deutschmann, Mr. N. C. Ridley, Dr. T. Harrison Butler and Dr. F. W. Eldridge-Green

Bequests and Donations.—The following bequests and donations have recently been announced:

Union Hospital, Terre Haute, Ind., $50,000 by the will of James McGregor.

Darrach Home for the Crippled, $5,000, State Charities Aid Association, New York, $1,000, donation by Charles H. Marshall, New York City.

Johns Hopkins Hospital, Baltimore, about $5,000 by the will of Albert A. McElroy of Washington township, Pa.

Railway Surgeons Meet.—The New York and New England Association of Railway Surgeons will hold its twenty-third annual meeting at the Hotel Astor in New York City, October 22. The address on "Surgery" will be delivered by Dr. Hugh H. Young, Baltimore. Dr. John W. Le Seur, Batavia, N. Y., is president and Dr. George Chaffee, 338 Forty-Seventh Street, Brooklyn, N. Y., the corresponding secretary of the association.

Lane Medical Lectures.—The fourteenth course of Lane Medical Lectures will be delivered in Lane Hall, San Francisco, on the evenings of September 3, 4, 5, 8 and 9 at 8 o'clock, by Prof. Sir Edward Schäfer, professor of physiology, University of Edinburgh. The several subjects are on "Internal Secretion in General," "The Thyro-Parathyroid Glands," "The Adrenal Glandular Apparatus," "The Pituitary Body," "The Influence of Internal on other Secretions," and "Methods of Resuscitation" (to be delivered at Stanford University, Cal.). The lectures will be illustrated by lantern slides.

Life Insurance Directors' Meeting.—The third annual meeting of the medical section of the American Life Convention was held in St. Paul, Minn., August 19, under the presidency of Dr. H. A. Baker, medical director of the Pittsburgh Life and Trust Company, Pittsburgh. The most important subjects discussed were the "Curve of Mortality" and the "Insurability of Women." The following officers were elected: chairman, Dr. James H. Stowell, Chicago, medical director United States Annuity and Life Insurance Company; vice-chairman, Dr. Whitfield Harral, Dallas, Tex., medical director Southwestern Life Insurance Company; secretary-treasurer, Dr. F. L. B. Jenney, medical director Federal Life Insurance Company, Chicago; board of managers, Drs. James H. Stowell, Chicago; Whitfield Harral, Dallas, Tex.; Ambrose Talbot, Kansas City; Frank W. Foxworthy, Indianapolis, and F. L. B. Jenney, Chicago. West Baden, Ind., was selected as the place for the mid-year meeting and Dallas, Tex., for the next annual meeting.

American Mine and Safety Association and American Mining Congress.—The annual meeting of the American Mine Safety Association will be held in Pittsburgh, September 22, 23 and 24, with headquarters at the Fort Pitt Hotel. The organization has been in existence less than a year. It was formed for the purpose of promoting safety for underground workers, miners and others. This is expected to be accomplished by recommending proper safeguards against accidents, approved appliances and methods of procedure in safety inspection, mine rescue work and first aid treatment, also by circulating information on these subjects and encouraging the miners and other underground workers to consider their own personal safety and that of their fellow workmen by the establishment of national first aid corps, such as St. John's Ambulance Corps of Great Britain. In 1911, 2,719 persons were killed in coal mines alone; 9,106 were seriously injured and 22,228 were slightly injured. Nearly an equal number were injured in metal mines and quarries. It will be seen that the organization of mine workers and operators and the promotion of everything that would conduce to the safety of men engaged in these underground occupations is important. In recent years much attention has been given to providing safety appliances for mines. The American Mining Congress, which meets in Philadelphia, October 20-24, for its sixteenth annual convention, will also have an exhibit of safety machinery and appliances for mines.

FOREIGN

Report of Philippine Government Employees.—Dr. Victor G. Heiser, Director of Health, furnishes the following abstract of statistics of the health of government employees in the islands: Total number employed, 10,010; Americans, 2,810; Filipinos, 7,200. Deaths from illness: among Americans, 5; among Filipinos, 23: from violence, Americans, 2; Filipinos, 1. Average years of service: Americans, 6.93; Filipinos, 5.47. Average age at death: Americans, 38.93; Filipinos, 32.01. Annual death-rate per thousand: Americans, 1.77; Filipinos, 3.19. Annual death-rate per thousand for all nationalities, 2.79. All deaths, including those from violence, average rate per thousand, 3.09.

CANADA

Public Health Congress.—The third annual congress of the Canadian Public Health Association will be held in Regina, Sask., September 18-20, under the presidency of Dr. John W. S. McCullough, Toronto, provincial health officer of Ontario. The congress will hold general sessions and also there will be section meetings dealing with medical officers of health, medical inspection of schools, military hygiene, veterinary hygiene and food inspection, sanitary inspectors, engineers and architects, laboratory and social workers. The general sessions are to be held in the Regina City Hall and the sectional meetings in the Regina College.

Queen's Medical Faculty.—The medical faculty of Queen's University, Kingston, Ont., has submitted an amendment to its constitution whereby, when approved by the board of trustees, all financial control and responsibility will pass from the faculty to the board of governors of the university. In the constitution of 1892, academic union was provided for, but the financial administration remained in the hands of the faculty. Twenty-one years ago when the staff of the Royal College of Physicians and Surgeons of Kingston became a faculty of the university, there were ten professors, one lecturer, one demonstrator and two arts professors who taught medical students. At the present time the staff consists of fourteen professors, four associate professors in two faculties, five assistant professors, six lecturers and eight clinical assistants and demonstrators, thirty-seven in all. During this period of twenty-one years, 750 have been graduated from Queens in medicine. That this school of medicine has progressed is seen from the equipment of twenty-one years ago. Then there were a few stoves, a number of tabls and a part of a skeleton in the dissecting room. There was not a microscope in commission. To-day there are more than a hundred. In the past session, the fifty-ninth, the registration amounted to 251, an increase of two over last year. The finances are in good condition, there being a cash balance over all indebtedness of $4,452.99.

LONDON LETTER

(From Our Regular Correspondent)

London, Aug. 2, 1913.

Sleeping-Sickness in Nyasaland

Surgeon General Sir David Bruce, head of the sleeping-sickness commission which was sent to Central Africa nearly two years ago to investigate the disease, has returned to England. The commission has made some important discoveries. It has found that the sleeping-sickness in Nyasaland is not the same as that of Uganda or the West Coast, although it belongs to the same category. It is more rapid and even more fatal. There has been no case of recovery. It is now established beyond doubt that the disease is carried by *Glossina morsitans*, a fly which is widely spread over the whole of Africa and is not merely confined to well-defined areas, like *Glossina palpalis*, which has hitherto been regarded as the carrier of the disease. Sir David Bruce's work has been carried on in a proclaimed district of Nyasaland on the eastern shore of the lake, extending 50 miles from north to south, and 25 miles from east to west. Animals were shot early in the morning, and specimens of the blood while perfectly fresh were carried back by motor-bicycle to the laboratory for examination. Half the wild animals shot in the area were found to be infected with sleeping-sickness in some form or other, and in all probability the whole of them may be said to be affected. The commissioners are of opinion that the game in these areas should be regarded in the same light as mad dogs and destroyed as a standing menace to natives and whites alike. Sir David Bruce's report has not yet been considered by the authorities, so it cannot yet be said what steps will be taken. The disease in Nyasaland and north and northeastern Rhodesia has been given the name of sleeping-sickness, but the work of the commission went to show that it was the old tsetse fly disease of the South African hunters, which was formerly supposed only to attack animals, but has now spread to man. Some regard the disease as a new one, but Sir David Bruce believes it to be the disease known over large areas as nagana and called by that name in the nineties. Human cases have been found not only in Nyasaland, but also in northeastern Rhodesia, Portuguese East Africa and South Zambesia, and in all probability other cases will be discovered wherever these flies are found, for it is proved that *Glossina morsitans* carries the disease known as nagana. Sir David Bruce does not believe that there is any danger of the disease spreading. He is of opinion that it has probably been in these areas from time immemorial and that it will never assume the terrible proportions of the sleeping-sickness of the Congo or Uganda. Camps were established [illegible]ses, but they were found to be of no [illegible] with the natives. As patients were often found when the disease had run two months of its course, and as they invariably died during the third month, the native naturally regarded the camps with suspicion, and accordingly sufferers were treated in the village.

The Control of Venereal Disease: Demand of the Profession for a Government Inquiry

In this country there is no system of examination and control of prostitutes, such as exists in other European countries. Consequently the state does nothing to prevent the spread of venereal diseases. The difference may be explained on two grounds. This country is more individualistic than others; the state interferes less in personal affairs. In the second place a strong objection exists among religious persons to "the state recognition of vice." In a letter addressed to the press a demand has been made by the leading men in the profession, including the presidents of the Royal Colleges of Physicians and Surgeons, Sir William Osler, Sir Clifford Allbutt and the principal dermatologists and syphilologists for some action on the part of the government. It is pointed out that the increase of medical knowledge during the last sixty years has been extremely rapid and the control of health problems by the state and municipalities has become one of the most striking features of modern civilization. The state has compelled local authorities to build asylums for the insane; it has encouraged them to make provision for the segregation of cases of infectious fevers; it has insisted on the notification of many infectious diseases; it has undertaken the inspection of schoolchildren on a colossal scale; it has introduced an elaborate machinery to insure the purity of foods; it is steadily building up a vast system of public health legislation. To-day we are looking forward to what may be the effects of the campaign against tuberculosis. In all this organized effort there is one notable omission. There has always been a conspiracy of silence with regard to venereal disease. When the subject was discussed last year at the Royal Society of Medicine it was stated that in London alone 40,000 new cases of syphilis occur every year. The disease claims its victims not only from the vicious but also from the innocent. We are living to-day in a new era as regards diagnosis and treatment. The microbes responsible for venereal diseases have been discovered. The time is threfore ripe for an organized effort on a comprehensive scale to reduce the incidence of these diseases. The experience of the army medical department has shown during the past few years that an enormous reduction can be brought about by systematic effort. Organized effort among the civilian population is impracticable until the public conscience has been aroused, and can be attempted only after a full and authoritative investigation. These leaders of the profession therefore appeal to the public to demand the appointment of a "royal commission" (a government commission), its members to include a substantial majority of physicians, to investigate and recommend what steps, prophylactic and therapeutic, should be taken to cope with these diseases. In reply to a question in parliament the prime minister said that the subject would receive the careful consideration of the government. It will be discussed at a meeting of the International Medical Congress by the leading syphilographers of this and other countries and is expected to excite so much interest that the section of dermatology, which meets at St. Thomas' Hospital, will be moved to meet for this purpose at the Albert Hall, the largest hall in London. Probably in anticipation of this the demand referred to before has been made.

PARIS LETTER

(*From Our Regular Correspondent*)

PARIS, Aug. 1, 1913.

The Campaign Against Tuberculosis

The Académie de médecine recently passed a resolution in favor of the obligatory reporting of tuberculosis, and it is beginning to be conceded that if such declaration is not to be a vain word, prophylactic measures are necessary. A bill has been presented before the senate for the foundation of public antituberculosis dispensaries for general antituberculosis education, the giving of advice with regard to prophylaxis and hygiene, for facilitating the admission of patients into suitable institutions and placing within the reach of the public disinfection service for clothing, dwellings and so on, rendered infectious by patients. Free consultations and distribution of medicine should also be provided for by the dispensaries. According to the senate bill the necessary funds will be looked for in part from private sources and in part from the government. When the number of deaths in the commune shall have exceeded the average mortality in France during three consecutive years, the foundation of an antituberculosis dispensary is to be obligatory. The commune, department and government are to bear the expense in equal proportion.

Aid for Large Families

A law has just been promulgated according to which every head of a French family, responsible for the expenses of more than three legitimate or recognized children, whose resources are insufficient to take care of them, is to receive an annual allowance for each child, after the third, who is less than 13 years of age. If the mother is responsible for the children on account of the death of the father or through his abandonment of the family, or for any other reason, the same assistance is to be rendered for each child after the first. If the mother is dead or has abandoned the family, the father is to receive assistance for each child after the second. Relatives who care for the children after the death or abandonment of father and mother are to be considered as heads of families.

Measures Against Flies

The Council of Public Hygiene and Health has had the prefect of police publish 500,000 copies of a circular to be distributed throughout France, giving advice in regard to the protection of food from flies, the excluding of flies from dwellings, the destruction of flies and the prevention of their reproduction. Posters, giving similar information, have been distributed and posted in Paris and in the provinces.

Necropsy Arranged by Will

Dr. Pinard, professor of clinical obstetrics in the University of Paris, and M. Barrier, inspector general of the veterinary schools, both of whom are members of the Société pour la propagation de l'incinération, have left instructions in their wills that their bodies shall be delivered to the Faculté de médecine for necropsy before being burned.

The Psychophysiologic Signs of Superior Skill among Typewriters

Recently M. J.-M. Lahy reported to the Académie des Sciences the results of his investigations of the psychophysiologic signs indicative of superior skill among typewriters. He classes his subjects according to the rapidity and exactness of their work, judged by the results of their copy of a text containing 1,702 characters. After this test, each subject was examined for memory of figures and phrases, attention, imagination, abstraction, judgment, reasoning, tactile and muscular sensibility, auditory reactions and dynamometric force. The conclusions are that abstraction, judgment and imagination seem to have no part in the superiority of typewriters. The constant characteristics in a general way among good typewriters are good memory for concrete phrases, a tendency to equal muscular strength of the two hands, well-developed tactile and muscular sensibility and sustained attention. Curiously, these experiments have shown in all the good subjects a relative slowness of auditory reactions, indicating that a relatively slow action, well coordinated, is preferable to one that is rapid but poorly coordinated.

BERLIN LETTER

(*From Our Regular Correspondent*)

BERLIN, Aug. 8, 1913.

Personal

Professor von Wassermann has been appointed director of the Kaiser Wilhelm Institute for Experimental Therapy.—— General staffsurgeon a.D. Dr. van Bestelmeyer died at Munich a few days ago.

Professor Rosenthal of Erlangen has resigned his position. Professor Weinland of Munich has been called as his successor.

Professor Hering of Prague has been called as director of the newly founded pathologic-physiologic institute, and Prof. R. Müller of Kiel, as director of the hygienic-bacteriologic institute erected at the Academy for Practical Medicine in Cologne.

Professor Dietrich, prosector at the public hospital in Charlottenburg, has been appointed director of the pathologic institute of the Akademie für praktische Medizin in Cologne.

Professor Schmieden, for many years assistant to Professor Bier, has been called to succeed von Bramann as director of the surgical clinic at Halle.

Minor Sanitary Measures Demanded by the Organized Profession

The business committee of the Berlin ärztliche Standesverein, the association representing the professional interests of Berlin physicians, at its last session adopted the following resolutions:

1. The management of the Berlin street car company is notified of the frequent violation of the street-car regulation prohibiting tearing off the street-car tickets from the block with the finger moistened with saliva, and is requested to secure the greatest possible abatement of this nuisance. The chief of police is also requested to secure the abatement of the similar nuisance in shops of moistening the finger with saliva in tearing off paper bags and wrapping paper.
2. The chief of police is also requested to take some action with reference to the nuisance so offensive to esthetic taste and to sanitary safety due to the pollution of the streets of Greater Berlin by dogs.
3. The business committee also petitions the authorities in charge of the municipal hospitals asking for an abatement of the evils connected with charges for treatment of ambulant patients in the hospitals.

The Work of the Berlin Medical School Inspectors

The number of Berlin public schoolchildren for the year 1911-1912 was about 225,000, the number of boys and girls being practically equal. About 34,000 children entering school for the first time were examined by the medical inspectors, an average of 680 for each school physician. Physical or mental unfitness for school was found in 9.72 per cent. as compared with 10.55 per cent. for the previous year. The causes were general debility (anemia) in 1,317; rickets in 377; scrofula in 140; bone tuberculosis in 77; pulmonary tuberculosis in 155; other lung diseases in 134; heart disease in 61; kidney disease in 5; nervous diseases in 133; epilepsy in 28; imperfect mental development (idiocy or feeblemindedness) in 75 and 440 respectively; disturbances of speech in 73; nose and throat affections in 7; eye diseases in 40; ear diseases in 26; skin diseases in 19; curvature of spine in 89; hernia in 8; deformities in 25; other diseases in 73. Thus, 47,619 children were placed under medical supervision, a percentage of 21.22 as compared with 21.4 in the previous year. For the schools for backward children and special classes for the feeble-minded, 1,133 children were examined. Of these, 925 children were assigned to the subsidiary schools, 103 were left in the common school, 14 were transferred to idiot asylums, 91 were placed under private instruction; 448 children were examined for the courses in stuttering and 174 children for the special classes for those hard of hearing.

THE DENTAL CLINICS

In the first Berlin school dental clinic the number of children treated was 11,950, in the second, 16,023. Here the attendance has increased about 3,000. In the newly opened third school dental clinic the subscription system was tried. The children subscribing are placed under dental treatment and supervision during the entire year. One mark per year is required for each child of well-to-do families; for all of the public school children of the same family, three marks. The city of Berlin has raised the appropriation for the school dental clinics from $3,750 (15,000 marks) to $6,250 (25,000 marks).

CONTAGIOUS DISEASES

On account of contagious diseases, 80 classes were closed during the year as compared with 40 in the previous year. In view of the occurrence of numerous very obstinate epidemics of diphtheria and scarlet fever, a circular has been prepared to be given to the children to take home when a case of contagious disease occurs among the scholars in the room in question.

Use of Meat

Professor Max Rubner, the well-known physiologist and hygienist of Berlin, has contributed a valuable article to the discussion of the meat question which has excited a good deal of agitated public discussion, not always according to the facts. He devotes a large amount of space to this question in his work just published entitled "Changes in the Food of the Masses" (Wandlungen in der Volksernährung). From the material which he brings forward he shows that there is no question of a lessening of the use of meat or of Germany falling behind other nations in this respect if we take into consideration a long period of time. At the present time the inhabitants of Australia are by far the largest meat eaters, consuming 111.6 kg. (250 pounds) per capita yearly. The consumption is only half as great in the United States (54.4 kg.). Then comes Germany (52.30), England (47.6), France (33.6), Belgium and Holland (34.3), Austria-Hungary (29), Spain (22.2), Russia (21.8) and Italy (10.4).

It is thoroughly false when the Englishman is pointed out as the beefsteak eater, for the German eats on the average somewhat more meat than the Englishman. Formerly his use of meat was markedly less and the following figures show how it has grown within a century. In 1816 Germany consumed per capita 13.6 kg.; in 1840, 21.6; in 1861, 23.2; in 1873, 29.5. Then occurred a temporary fall in 1883 to 29.3, followed by a rise in 1889 to 32.5; in 1900 to 43.3, and in 1907 to 46.2. At present the use of meat is 3.4 times as great as it was a century ago. In 1813 the consumption of meat in Germany was about the same as it is to-day in Italy, the country that uses the least meat of any in Europe. To be sure, there is at present about as great a difference between city and country, the cities consuming the most meat. The average consumption in the cities is 52.4 kg. per capita annually as compared with 31.6 kg. in the country. All the cities, although the consumption of meat varies very much among them, are above the average of the country districts. The least meat is used in Königsberg (40.7 kg.) while there is a large consumption in Berlin, Karlsruhe and Mannheim (70.9 kg.) and the largest in Munich, Augsburg and Nuremberg (80.2 kg.). A large consumption of meat was also characteristic of Munich in the past. The bulk of the meat is consumed by artisans, the so-called upper classes eating only one-seventh. Rubner divides the use of meat among the trades as follows: Farm and day laborers, 16.5 per cent.; artisans, 44.8; the lower middle class, 15; the middle class, 10.5, and the higher class, 12 per cent. The increase in meat consumption is to be attributed to the more frequent use by the lower classes.

Vital Statistics of Prussia 1911-1912

In the state of Prussia during 1911, there were reported 1.225,091 births, 732,728 deaths (including 35,874 still-births) and 321,151 marriages. The excess of births was 492,363 or 12.1 per thousand of the average population. In 1912, there were born according to the previous sources of information 1.219.867 children (including still-births) and there were 671.909 deaths. There were 328,415 marriages. According to this, the number of births was 5,224 less than the previous year and the number of deaths 60,819. The excess of births accordingly had increased by 55,595, an increase from 492,363 to 547,958. An especially striking feature of last *year's statistics is the decreasing* number of births with an increase in the number of marriages. While during the decade from 1902-1911 the number of births was on the average, 1,284,110, the number of deaths, 725,241, the excess of births, 558,869, the number of births in 1911 was already 59,019 below the average of the decade, and in 1912, 64,243. The number of deaths in 1911 was 7,487 above the average of the decade but in 1912 remained 53,332 below the average of the decade. The number of marriages in 1911 was 17,631 above the average It of the decade from 1902 to 1911 and in 1912 it was 24,895. is consequently evident that the fertility of married women has suffered a not inconsiderable reduction. While the birth-rate has sunk about 18 per cent., the death-rate until 1911 had diminished about 11 per cent. and was in the last year about 22 *per cent.* lower than in 1903. The marriage-rate for 1912 agrees with the average for the decade, 16

SEVENTEENTH INTERNATIONAL MEDICAL CONGRESS

August 6-12, 1913

(From Our Regular and Special London Correspondents)

(Continued from page 613)

The Garden Party at Windsor

The great event of the Congress in the way of entertainment was the Garden Party given by His Majesty the King at Windsor, on Saturday, August 9. The invitations were limited to 2,000. Four special trains from Paddington station carried the guests to the main entrance to the Castle where the Lord Chamberlain, the Comptroller of the Household and other officials received them on behalf of the King. The visitors then passed rapidly into the Great Quadrangle and proceeded to follow a steward through the whole of the State Apartments used by His Majesty when entertaining sovereigns on visits of state. Entering the vestibule the guests were conducted up the grand staircase into the state anteroom, decorated with exquisite carvings of fish, fruit and game, by Gibbons. Passing thence through the picture gallery containing masterpieces by Rembrandt, Holbein, Claude, Andrea del Sarto and many other masters, the Van Dyck Room (formerly the Queen's ball room) was reached, decorated entirely by works of Van Dyck. The Queen's audience chamber, decorated with fine Gobelin tapestries executed for Louis XIV from designs by Jean Francis de Troy, representing the history of Esther, was then traversed into the Queen's presence chamber. Thence through the grand room the visitors entered the magnificent St. George's Hall, decorated with the shields and banners of all the knights of the order from its foundation. The grand reception room, where guests are received for banquets in St. George's Hall, came next. It is decorated with Gobelin tapestries representing the story of Jason and Medea. On the left the throne room, hung in blue velvet, was entered. It contains a silver gilt throne ornamented with cut crystals, formerly the state chair of the King of Candy. Passing through the ante-throne room, the Waterloo chamber, the grand vestibule and down the grand staircase again, the visitors were ushered through the Italian Gardens, where the band of the Coldstream Guards was playing, on to the east lawn, a magnificent pleasance where tea was prepared in large marquees. The tables were decorated with roses and carnations from the royal gardens, and besides tea and coffee, champagne and other beverages were abundantly forthcoming and the most dainty delicacies and confections were served. The guests scattered about through the pleasance or gathered in groups greeting old friends and making new ones until 6 o'clock, when, after viewing the Albert Memorial Chapel and St. George's Chapel they returned to town in special trains, arriving soon after 7 o'clock after a unique day of beautiful weather.

The same evening (Saturday) Sir Lauder and Lady Hamilton entertained a large party of the more eminent foreign visitors to dinner at the British Empire Club.

Dr. Norman Moore, president of the historical section, also entertained about thirty of the section at a dinner. The dinner of the Section of Obstetrics and Gynecology also was held on Saturday evening, August 9.

Church Services Sunday

On Sunday morning, August 10, a large number of members of the Congress attended the special services at St. Paul's Cathedral (Anglican), where the sermon was preached by the Dean, the Rev. Dr. Inge, at Westminster Abbey (Anglican), where Bishop Ryle preached, or at Westminster Cathedral (Roman Catholic) where Cardinal Bourne preached. The theme in all cases had reference to the intimate connection between the functions of the priest and the physician. Dean Inge, however, struck a very modern note when he impressed on his hearers the importance of throwing the weight of their influence into matters of state. Bishop Ryle adverted favorably to the movement in favor of facing the subject of venereal diseases. The service at the abbey was marred by unseemly interruptions from suffragettes.

Other Sunday Happenings

An excursion to Harrogate, one of our British spas, and an invitation by the Council and Medical Fellows of the Zoological Society to some 2,000 members to visit the garden, where numerous informal lunch and tea parties took place, provided for some of the visitors. About 500 were entertained by Mr. and Mrs. Waldorf Astor at their seat at Cliveden, one of the most beautiful spots on the Thames, where tea was served on the terrace to the music of the band of the Coldstream Guards. The Physiologic Section gave a river picnic on the Thames and Sir Watson and Lady Cheyne entertained about 200 of the Surgical Section at a river party starting from Taplow. Another delightful trip was that of the Electrotherapeutic Section of the Royal Society of Medicine, who took about 160 up the Thames from Westminster Bridge to Sunbury, providing luncheon and afternoon tea. The Anesthetic Section also had a luncheon at the Zoological Gardens. The Sections of Rhinology and Laryngology and of Otology took 300 ladies and gentlemen of the Congress to Oxford.

Honoring Lord Lister and Sir Patrick Manson

Monday's Events

A graceful tribute was paid on Monday, August 11, when the French members of the Congress accompanied Dr. Lucas-Championnière to the Royal College of Surgeons and placed a laurel wreath entwined with roses on a new bust of Lord Lister specially executed for the college by Sir Thomas Brock, R. A. Another foreign tribute to British scientific work was the presentation in the Section of Tropical Medicine and Hygiene on Monday to Sir Patrick Manson of a medallion in gold, bearing his profile, the work of M. Richer, of Paris.

Entertainments on Monday showed no sign of slackening. An excursion to Stratford-on-Avon, a visit to the Middlesex Hospital, garden parties at the London, Guy's and University College Hospitals and at the Hill, Hampstead Heath, found occupation for 2,500 members and their ladies. In the afternoon the nine medical Masonic lodges of London welcomed their foreign Masonic brethren at a special lodge held under the banner of the Aesculapius Lodge, No. 2410, at Freemason's Hall, when about 150 members of English medical lodges and officials of the Grand Lodge of England and 100 visitors from all parts of the world attended. The Pro-Grand Master of England, Lord Ampbhill, presided, and addressed the lodge, reading a letter from the Grand Master, the Duke of Connaught, regretting his inability to be present. The representatives of the various nationalities replied, Bro. C. M. Green, P. D. G. M., of the Grand Lodge of Massachusetts, speaking on behalf of the Masons of the United States.

In the evening the President of the Congress, Sir Thomas Barlow, gave a dinner at the Savoy Hotel at which 200 distinguished British and foreign members were present, as well as the Lord Chancellor, the Archbishop of Canterbury, the Archbishop (R. C.) of Westminster, the American Ambassador and Lord Strathcona. Later Lord and Lady Strathcona's garden party was attended by upward of 5,000 visitors in the beautiful grounds of the Royal Botanical Society, Regent's Park. The scene was enchanting.

Other entertainments on Monday evening were the dinner of the Royal Army Medical College to naval and military surgeons from abroad, and a conversazione and reception of members of the Dermatological Section in the Princes' Restaurant, Piccadilly.

On Tuesday, August 12, there were half-day excursions to Cambridge, Oxford, Canterbury and Farnham.

Sir Frederick and Lady Eve gave a garden party at Kew and the President of the Stomatological Section, Mr. Morton Swale, one at Henley. The members of the Section on Diseases of Children paid a visit to Queen Mary's Hospital for Children, Carshalton. In the evening the Sections of Rhinology and Laryngology and of Otology gave a combined dinner at the Hotel Cecil to which ladies were invited.

International Association of Orthopedic Surgery

An International Association of Orthopedic Surgery was decided on during the Congress and a committee has been found to attend to its organization. The committee consists of the following representatives, all of whom have attended the Congress: United States, Prof. R. W. Lovett of Boston; Great Britain, Mr. Robert Jones of Liverpool; Holland, Professor Murk Jansen of Leyden; Italy, Professor Putti of Bologna; France, Professor Kirmisson of Paris; Germany, Professor Vulpius of Heidelberg; Hungary, Professor Dollinger of Budapest; Canada, Professor Clarence Starr of Toronto; Russia, Professor Turner of St. Petersburg; Austria, Professor Spitzy of Vienna, secretary.

Esperanto Medical Association

The Universal Esperanto Medical Association (Tutmonda Esperanta Kuracista Asocio) held two meetings in the Geological Laboratory of the Royal School of Mines, under the presidency of Dr. Jameson Johnston of Dublin. At the first meeting on August 8 Dr. Johnston delivered an address on the "Need for a Common Language for Mutual Understanding in Congresses and the Use of Esperanto in Medicine." Addresses were also delivered in English, French, German, Russian, and other languages on Esperanto and the medical profession, and a number of recruits were made. The second meeting, on August 11, was taken up with the discussion in Esperanto of highly technical subjects.

Report of Permanent Commission and Award of Prizes

At the closing meeting, held in the Albert Hall on August 12, the Permanent Commission of the Congress presented its report. Besides resolutions urging governmental intervention in regard to syphilis by all the nations officially represented at the congress, protesting against any interference with animal experimentation, urging the disuse of overmilled rice and the abolition of quarantine in regard to beriberi, and changing the name of Malta fever to that of undulant fever, the report recommended the acceptance of Munich as the place of the next Congress, to be held in 1917, and nominated Prof. Dr. Friedrich von Mueller as president-elect. It also announced the award of the Congress prizes, as follows: The Moscow prize to Prof. Charles Richet of Paris, for his work on anaphylaxis. The Paris prize to Prof. A. von Wassermann of Berlin, for his work on experimental therapy and immunity. The Hungary prize to Sir Almroth Wright of London, for his work on anaphylaxis.

Hon. John Burn's Address

On the closing day at the Albert Hall Hon. John Burns, president of the Local Government Board, delivered an admirable address on the "Relationship between Medicine and Public Health."

Address on Heredity

On Monday, August 11, Professor Bateson, F.R.S., of Cambridge University, delivered an address on Heredity in Jehangir Hall of the University of London. After a tribute to the penetrating foresight of Francis Galton, Professor Bateson said that by accurate genetic analysis the means was afforded not merely of elucidating the inter-relation of parent and offspring, but also of contributing to a right interpretation of various special problems of pathology and anthropology, a true understanding of the course of human history, and the direction and control of the progress of mankind. The essence of the Mendelian principle was (1) that in a great degree the properties of organisms were due to the presence of distinct detachable elements separately transmitted in heredity; and (2) that the parent could not transmit to the offspring any element or its corresponding property which it did not itself possess. After reviewing the fundamental facts of the Mendelian doctrine, and showing that the presence or absence of a given property might be due to either a positive or a negative character, Professor Bateson pointed out that the American students of genetics had made it clear by evidence that feeblemindness had at least one mark of a recessive condition. But while the mental deficiency bill was a movement in the right direction, the violent measures now being adopted in some of the United States (e. g. Pennsylvania and New Jersey) gave ground for some disquietude. It was one thing to check the reproduction of hopeless defectives; it was another to recognize a wholesale tampering with the structure of a population such as would follow if any marriage not regarded by officials as eugenic were liable to prohibition. Nothing yet ascertained by genetic science justified such a course, and we might wonder how genius and the arts would fare in a community constructed according to the ideas of such legislators. There was a danger that in ridding the community of mania we should leave it gravely affected with dulness. The genetic analysis of insanity was at present practically impossible because the diagnosis of its various forms was by no means clear, and the conditions of life had obviously much to do with the development of such weaknesses. The tendency of the work of genetics was more and more to exhibit the fixity and definiteness of the laws of descent. Evolutionary change was effected not so much by gradual transformations under ameliorating or detrimental conditions, but mainly by the occurrence of individual or sporadic variation. The direction in which genetic research points was not difficult to determine. Those who had some knowledge of genetic physiology were aware that the whole form of modern science and legislation had hitherto been exercised in the preservation of defective strains, and would not feel serious hesitation as to the true cause of the increase of lunacy pointed out by Sir James Crichton Browne as running in certain decades.

Discussion on Internal Secretions

(Continuation from last week of report of Medical Section)

Friday morning, August 8, was held a joint session of the Section of Medicine with the Section on Physiology to discuss "The Correlation of the Organs of Internal Secretion and Their Disturbances." Prof. Sir E. A. Schäfer was in the chair. The discussion was opened by Prof. E. Gley of Paris, who gave a résumé of the methods by which the existence of internal secretions could be determined. He pointed out a fact that is overlooked by too many of the workers in this field of physiology, that one cannot take it as proved that the substances found in the extracts made from organs were present in these organs during life. These extracts were often highly toxic, but it must not be assumed that the toxicity was due to specific substances secreted by the organ; the toxicity depended on many conditions, and most of all on the method by which the extract had been prepared. Among other topics, he dwelt on the phenomenon of tachyphylaxis, exhibited when an animal's tissues acquire the property of resisting a second toxic injection within a few minutes or hours, while the first injection had found these tissues unprepared and open to attack. The reciprocal actions of the various ductless glands were of course, he admitted, extremely complex and hard to disentangle; he looked for solution of these problems to laborious physiologic and clinical work in the future. Several succeeding speakers—Professor Biedl of Vienna, Professor von Korányi of Budapest, Prof. F. Kraus of Berlin—read papers dealing with generalities and matters of detail that lend themselves little to condensation in such an account of the proceedings as this. Professor Cushing of Harvard gave an admirably clear and well-illustrated account of much of his own experimental and clinical work on disorders of the pituitary body. He exhibited slides of dogs whose pituitary bodies had been removed, and followed them with slides of human beings presenting very analogous—*mutatis mutandis*—syndromes. The adiposity and infantilism characteristic of Frölich's syndrome might, to some extent at any rate, be inherited; a photograph was exhibited showing a grandmother and a mother who both presented several of the outward features of the syndrome, while the daughter, just the sort of child one would have expected of such an ancestry, exhibited the syndrome in all its completeness. Professor Cushing brought to the attention of his audience a new type of dyspituitarism; the patients of this type are thin instead of being fat, but exhibit the same loss of secondary sexual characteristics (though perhaps by retrogressive change) as the patients of the commoner adipose type. He referred to several other types of dyspituitarism, and showed how in some the disease had been diagnosed as myxedema, and had received the appropriate treatment without benefit. He had found that the exhibition of pituitary extract improved these patients, and he took such a therapeutic success to be evidence of the correctness of his diagnosis. Another patient, a girl of 6, looked as if she were 16 years old; she had menstruated from the age of 2, and the secondary sexual characteristics had made their appearance when she was 3. He pointed out in conclusion that further researches into the functions of the pituitary gland would very likely throw light on the physiology of sleep; they had already done something to illuminate the etiology of hibernation. Other points in the correlations of the ductless glands were brought out by other speakers, including Professor Herring of St. Andrews, Dr. Falta, Dr. Blair Bell of Liverpool, Prof. Swale Vincent, Prof. G. Murray of Manchester, Professor Morsaline of Buenos Aires, and others. Professor Gley, in replying to a number of the points raised, took occasion to emphasize that hyperplasia of a gland, of the suprarenals in granular kidney, for example, was not necessarily equivalent to its functional hyperactivity, an assumption often made. The hall in which the meeting took place was crowded to its utmost capacity, and the discussion reached and maintained an unusually high level of excellence.

The afternoon session (August 8) was devoted to the reading of three papers. The last of these, by Dr. Haven Emerson of New York, dealt with the occurrence of the status lymphaticus in adults. The general public comes to hear of this uncommon condition from time to time through the coroner's court; for the children or adolescents who suffer from status lymphaticus or lymphatism are those who are apt to die suddenly while under the influence of an anesthetic. Dr. Emerson brought forward a number of considerations to show that a milder degree of lymphatism is surprisingly frequent in the adolescents and adults treated for chronic alcoholism and mental disease. His facts and figures are drawn from 1,000 of the male patients admitted to the alcoholic wards of the Bellevue Hospital, New York: No less than 220 of these patients showed most if not all of the physical attributes characteristic of the status lymphaticus. The chief of these attributes are as follows: Scantiness or absence of the hair on the lip, chin, chest, axilla; a feminine type of distribution of the pubic hair; a tendency to narrowness and length in the thorax; a notable roundness and arching of the thighs and roundness of the upper arm; smallness of the penis and testes. Often the skin is peculiarly soft and velvety, and curiously free from hairs. Dr. Emerson failed to find the enlargement of the spleen that is so commonly said to occur in lymphatism. Examining the post-mortem records he found 288 cases of lymphatism in 3,600 autopsies, and 242 of these patients had succumbed to infectious diseases such as tuberculosis, pneumonia, meningitis, enteric fever. He draws the conclusion that persons with this mild type of lymphatism are bad subjects for surgical operations, are prone to die if they contract an infectious disease, and show a tendency to alcoholism and insanity. He does not go so far as to say that they are social undesirables, but thinks that they should be protected against infections and against themselves.

Discussion on Heart Troubles

A first-rate discussion on "The Pathology of Heart-Failure" during the morning session Saturday, August 9, was opened by Prof. H. Vaquez of Paris, who began with an account of the various methods of clinical investigation and the symptoms that tell one when heart-failure is to be expected or diagnosed. The chief of these were acceleration of the pulse-rate, fall in the arterial blood-pressure, changes in the cardiac rhythm (and particularly the appearance of certain forms of irregularity), and alterations in the form of tracings furnished by the electrocardiograph. Employers and interpreters of the electrocardiograph, however, should not permit zeal to outstrip discretion, and attempt to draw from the electrocardiogram deductions more precise than our present knowledge warrants. Examination with the x-ray, especially when repeated from day to day, gave more valuable information about heart-failure than any other method. Failure of the heart might be either partial or total, and might affect different chambers of the heart in different cases. Thus failure of the auricles was not rare in mitral disease, and often really seemed to make but little difference to the patient. Failure of one or other of the ventricles of the heart was commoner; failure of the left ventricle was the cause of those painful palpitations and attacks of painful dyspnea that frequently occurred toward the end in severe cases of heart-disease, and often brought with them sudden death. Primary failure of the right ventricle, contrariwise, was characterized by quite other features — painless shortness of breath on exertion, with only a slight increase in the rate of the pulse. Total cardiac failure involving all four chambers together was rare; it might occur in healthy persons after prolonged and violent muscular exertion — in Marathon runners, for example. But it might also occur, oddly enough, in the pot-house patrons of such athletes, or in those who drank vast quantities of beer (the Munich or Tübingen beer-heart, so-called). Professor Vaquez and Professor Wenckebach, who followed him, believed that our prognosis in cardiac disease was so often unsatisfactory, or even totally wrong, because the trouble was due to debility of the heart-muscle, and because of our inability to form any correct clinical estimate of the degree of this debility. Arhythmia had been pointed to as an index of the impairment of cardiac muscle, but this was a mistake; arhythmia indicated impaired cardiac mechanism, and told us nothing about the functional competence of the muscular substance of the heart. In fact our only way of estimating the reserve power of the myocardium was the very unsatisfactory one of watching the progress of the malady. Professor Wenckebach expounded a method of measuring the reserve of cardiac power by estimations of the contractility of the heart-muscle; the method, however, though of great theoretical interest, did not admit of any practical application at the bedside.

Prof. W. T. Ritchie of Edinburgh next drew attention to "auricular flutter," a condition akin to auricular fibrillation. When fluttering, the cardiac auricles beat from 200 to 350 or even 380 times a minute; the ventricles often follow at only half that rate. He quoted cases to prove that neither auricular flutter nor auricular fibrillation deserve the gloomy connotation so commonly ascribed to them. They might last for years without harming the patient, and their establishment might even be associated with improvement in his general condition. Dr. L. F. Bishop of New York struck out a new line by attributing heart-failure to protein poisoning, and proposing to treat it by dieting and exhibiting repeated full doses of castor oil; Dr. Haig of London attributed heart-failure, *secundum artem*, to uric acid and nothing else. Of the other speakers several drew attention to the care that should be exercised in giving a bad prognosis in cases of morbus cordis. To diagnose "weak heart" as was so often done, was almost always wrong, as Professor Thayer of Baltimore, pointed out. Dr. Walsh of New York emphasized the importance of encouraging cardiac patients to think as well of their physical condition as possible.

Dr. E. Libman of New York read an account of a new form of subacute bacterial endocarditis which occurs mostly in persons who already have chronic valvular disease, a fact that suggests a relapse perhaps, rather than an infection with a new variety of microbe. The cases last from four to eighteen months, and in the great majority of cases end fatally; a few spontaneous recoveries and a few recoveries attributed to various forms of treatment have, however, been recorded. The microbe causing the endocarditis he had isolated in seventy-three out of seventy-five cases; it was almost always a streptococcus of a peculiar type, intermediate between the pneumococcus and the ordinary streptococci, and he proposed to name it the *Streptococcus mitis*. A special form of glomerular nephritis was characteristic of this new variety of endocarditis, and this was illustrated by lantern slides and explained by Dr. Baehr of New York, who was associated with Dr. Libman in his work. A special interest attaches to this form of heart disease because, as Dr. Poynton of London pointed out, it seemed to be very closely connected (if not indeed identical) with a form of rheumatic endocarditis described by himself and Paine in 1900. So far as Dr. Libman's investigations went, however, it appeared that *S. mitis* was not the same as the strains of the rheumatic diplococcus he (Dr. Libman) had been able to lay his hands on for purposes of comparison.

At the afternoon session a new and fairly simple method of obtaining simultaneously tracings of the arterial pulse, the venous pulse, and the heart-sounds was explained by Dr. R. Ohm of Berlin. Dr. Ohm's tracings showed clearly that his apparatus would be of considerable assistance in the diagnosis of certain forms of valvular heart-disease, and also for didactic purposes.

Diplococcus Endocarditis

Drs. A. Paine and F. J. Poynton of London next presented a summary of their recent work on rheumatic endocarditis. It was pointed out that the rheumatic diplococcus was capable of producing in man every form of endocarditis from the most benign simple variety to the most malignant. In animals, similarly, every variety of endocarditis could be produced by the intravenous injection of cultures of the diplococci taken from cases of rheumatic fever in human beings. Many forms of non-suppurative arthritis could be produced in animals, and a number of pictures were thrown on the screen showing the extensive circumarticular fibrosis and inflammation commonly produced; while others illustrated the fact that a typical rheumatoid arthritis, with lipping of the bones and erosion of the cartilages all complete, may result from such experimental infections of the joints in rabbits. A striking set of pictures illustrated the acute appendicitis that may follow, again in the rabbit, on the intravenous injection of rheumatic diplococci. Twenty rabbits six weeks old were inoculated with the organisms obtained from a case of rheumatic fever; nineteen developed polyarthritis, four appendicitis, one endocarditis. Microscopical sections of the inflamed appendices made it obvious that the rheumatic appendicitis of the young rabbit is in every way a replica of acute non-suppurative appendicitis in man. Necrosis of the lymph-nodules towards the periphery of the rabbits' appendix was conspicuous, followed by necrosis and disintegration of the greater part of the Lieberkühn's follicles and crypts opening into the lumen of the tube. Dr. Paine laid stress on the rapid phagocytosis of the organisms that takes place in both rheumatic rabbit and rheumatic man. He held that it accounts for much of the difficulty experienced by so many observers in isolating the rheumatic diplococcus from rheumatic patients.

Observations on the Venous Pulse

Dr. A. D. Hirschfelder of Baltimore next read his paper on various simple modes of diagnosing circulatory troubles that are commonly believed to require the use of expensive and complicated pieces of apparatus for their demonstration. Among the points he dealt with was the naked-eye observation of the venous pulse at the root of the neck. By laying the patient horizontal the internal jugular vein can generally be made to stand out in relief on the surface of the neck. Its edge and its pulsations can be thrown into relief by holding the margin of a white visiting-card parallel to its course and in close proximity to its border. This white card gives a fixed point that appears to amplify and at the same time define any pulsations that the vein may show. He illustrated the use that might be made of these pulsations in the diagnosis of various forms of irregular cardiac rhythm. For example, auricular extrasystoles can be seen to occur in pairs; ventricular extrasystoles singly, and he noted that these produce extremely large and forcible venous pulsations; in complete heart-block the number of extra auricular systoles intercalated between the ventricular beats varied in successive diastoles and was inconstant.

Discussion on Diabetes

The Monday, August 11, morning session was occupied by a very satisfactory discussion on diabetes mellitus. The subject was introduced by Dr. G. Dock of St. Louis, who went fully into the different views that have been published in the hope of clearing up its etiology. The connection of diabetes with the pancreas is well known; perhaps too much attention is paid to the pancreas in diabetes, and too little to the other organs of the body. The control exercised by the central nervous system on the sugar-producing functions of the liver is better recognized nowadays than it used to be; the fact that many spots in the brain, besides the diabetic center of Claude Bernard, give rise to diabetes on puncture, was not sufficiently recognized. Reference was made to Cushing's admirable work on the pituitary gland; its posterior lobe plays an important if indefinite rôle in the metabolism of the carbohydrates, and its glycolytic function appears to be under the control of the superior cervical ganglion of the sympathetic. Acidosis, the terminal event that brings on diabetic coma in so many cases of diabetes, was connected with decrease in the amount of carbohydrate in the diet, increased fat-metabolism, and increase in the formation of sugar from the proteins of the bodily tissues. In the treatment of the disease, now mainly a matter of dieting, it was important to secure the attention and intelligent help of the patient. Prof. C. von Noorden of Vienna followed, and gave a first-rate account of the most recent views of the way in which the carbohydrate metabolism of the body is regulated. Needless to say, this regulation is highly complicated. Professor von Noorden presented to his audience a diagrammatic scheme in which the control of the glycogenic function of the liver was set out. The pancreas is the organ that tends to keep the consumption of sugar down, the chromaffin system (or, to mention its chief constituent, the suprarenal gland) tries to increase the consumption. But the pancreas is in turn controlled by the thyroid gland, the parathyroids, and the hypophysis; while the chromaffin system is under the control of the central nervous system. All of these controls, except that of the central nervous system, are exercised by the medium of the secretion of the various glands concerned, conveyed about the body by the blood-stream. The regulation of the glycogenic function of the liver by the pancreas and chromaffin system in the normal subject is such that the blood contains from six to eight parts of glucose per ten thousand. In diabetes this quantity is increased, either because the inhibiting power of the pancreas is weakened, speaking generally, or because the augmenting power of the chromaffin system is increased. In Claude Bernard's diabetic puncture of the brain, for example, the glycosuria is due to the central stimulation of the chromaffin system. Acidosis is fatal by removing the ammonia and alkaline bases from the body in excessive amounts; diabetic coma is the expression of alkaline poverty of the tissues. Coming to the treatment of diabetes, Professor von Noorden said that drugs are but little given to diabetics as such nowadays; the treatment consists almost entirely in setting each patient to live on exactly the diet that suits him best. A sugar-free diet is first given to reduce the glycosuria to the lowest possible value; in favorable cases the sugar disappears from the urine. The next step is to ascertain by direct experiment what is the limit of the patient's tolerance for carbohydrate; sugary or starchy foods are added cautiously to the dietary, and their effect in producing glycosuria is carefully watched. These tolerance tests require the constant supervision and regulation of the physician. It is most important that the body's sugar manufactories should at no time be overburdened; the urine must be kept as free from sugar as possible, or the disease will progress. Too much must not be expected from such treatment; there always will be cases of diabetes mellitus that progress in spite of the greatest care, because the lesions on which the disease depends are sometimes inevitably progressive. In severe cases he advised the adoption of alternating periods of carbohydrate feeding and carbohydrate starvation. Most cases should have plenty of fat in their diet; in severe cases two or three ounces of whisky should be given every day. Professor von Noorden described his well-known "oatmeal cure," which was found to do good, but for what reason was not understood. Banana cures and flour cures, worked on similar lines, had also been employed successfully. Dr. Cammidge of London introduced a new urinary test—the iodin coefficient of the urine—whereby it was possible sometimes to foresee some weeks beforehand the appearance of sugar in the urine of a patient with pancreatic disease. Lieut.-Col. K. Prasad, I.M.S., gave an account of diabetes in India; it is not a rare disease among the Hindus, and their medical men treat it mainly by drugs that soothe the nervous system. Dieting did not occupy a large place in the treatment, and only a very mild degree of limitation was put on the consumption of carbohydrates. An uniformly bad prognosis was given. Dr. Labbé of Paris was on well-trodden ground when he read a paper proposing to divide diabetics into two classes clinically, the fat diabetics and the thin. Professor Saundby of Birmingham spoke of a number of practical points that should be kept in mind by practitioners who have to treat diabetes. He urged that too much meat should not be given, for too much meat was almost as bad as too much carbohydrate. It was important to remember that many of the diabetic foods advertised as free from starch were not by any means free from it; fraudulent manufacturers of such foods were only too common. He could not agree with Professor von Noorden's advice to give large quantities of alcohol to these patients.

Upholding Vivisection

At the beginning of the morning session, Tuesday, August 12, the president, Sir William Osler, put to the crowded audience a motion affirming the importance and necessity of vivisection, carried out, as it is, under due control, for the progress of medical science. The motion was carried unanimously.

Discussion on Arthritis

Prof. L. F. Barker of Baltimore opened the day's discussion on "The Differentiation of the Diseases Included Under the Title Chronic Arthritis." Professor Barker gave his hearers an exhaustive survey of the history of the nomenclature that has burdened and confused these chronic joint-troubles. In the earliest days any acute disease of the joints was called arthritis, any chronic disease was called gout. G. D. Baillou about 300 years ago reversed this, describing chronic conditions as arthritis, acute inflammations of the joints as rheumatism. Rheumatoid arthritis was a name invented in 1859 by Garrod. Many classifications of chronic arthritis had been attempted on pathological or etiological or morphological bases, or, worse still, by the employment of mixed criteria. He distinguished five main types: (1) the gouty; (2) the nervous; (3) arthritis deformans; (4) chronic infective arthritis; (5) primary progressive chronic arthritis apparently not due to any infection. He dwelt on the fact that in proportion as our knowledge increases, so are we able to transfer cases from group (5) with its unknown etiology, to group (4) in which the bacteria causing the arthritis are known. Complete knowledge, he believed, would some day enable us to empty group (5) into group (4) altogether: at present, however, this could not be done. It was a remarkable thing that cases falling into group (5) had been reported from all countries. He was followed by Prof. F. von Müller of Munich, who gave a very full and most instructive account of the pathology of chronic arthritis. A special feature of his address was the skill with which he figured on the black-board the many morbid changes that might be met with in such conditions. A number of the observed changes were of a degenerative rather than inflammatory nature, particularly in those forms of chronic arthritis in which hypertrophy is a marked feature. He drew attention to the curious arthritic and periostitic changes not rarely met with in patients suffering from noninflammatory mediastinal new growths. Dr. Preston King of Bath deplored the unhappy terminology employed in descriptions of chronic arthritis, and agreed with Professor Barker in believing that his fourth and fifth groups would one day be merged. Professor Singer of Vienna spoke of the care needed in discriminating those cases of chronic arthritis due to tuberculosis or syphilis from the other varieties. Dr. J. B. Burt of Buxton emphasized the important actions of exercise and work in determining the exact nature of the changes produced in chronically inflamed joints. Similar changes (he called the phalanx of a London cab horse to witness) might be produced by overwork alone: he asked how many of the hypertrophic changes in the bones of chronic arthritis might well be due to the work done, the use made of the joint, and not to the inflammation at all?

Dr. Hale White of London expressed his belief in the unity and existence of a chronic arthritis that has been recognized in this country for more than half a century under the name of rheumatoid arthritis. It was correctly placed by Professor Barker in his fifth group of cases: Dr. Hale White believed that it was due to a specific microbe that had never been isolated hitherto, and pointed out that the primary change, seen in early cases of rheumatoid arthritis, was confined to the synovial membrane. Dr. Poynton of London pointed out that whereas in days gone by chronic arthritis was attributed to errors of metabolism, at the present time the tendency was to attribute it to infection in every case. He believed that the truth lay somewhere between these two views. Injected intravenously into the rabbit, the rheumatic diplococcus isolated by Paine and himself was capable of producing any and every variety of chronic arthritis; further, the effusions withdrawn from such joints would often prove sterile, although one could have no reasonable doubt that they were in reality infected with the rheumatic streptococcus. Dr. A. E. Garrod of London deprecated the want of an international nomenclature, by the use of which the confusion at present reigning in the description and classification of cases of chronic arthritis by the writers of different nationalities now prevalent might be got rid of. Modern treatment was undoubtedly better than the old, as was proved by the smallness of the number of severe types of chronic arthritis to be seen nowadays.

(To be continued)

Marriages

Henry Carl Richter, M.D., U.S.P.H.S., Calexico, Cal., to Miss Carrie Harrison Hamill of Globe, Ariz., at San Diego, August 4.

Robert Blucher McCay, M.D., to Miss Nellie Glenn Farnham, both of Sunbury, Pa., at Philadelphia, August 18.

Charles W. Huff, M.D., Jackson, Wyo., to Miss Edna R. Cearfoss of Baltimore, at Cheyenne, Wyo., June 16.

Joseph James Rowan, M.D., to Miss Alice Butterfield, both of Dubuque, Ia., at Cedar Rapids, Ia., August 11.

Otto John Hermann, M.D., Boston, to Miss Alice Hamilton O'Connell of Jamaica Plain, Boston, August 18.

Luther Milton Powers, M.D., to Mrs. Mary R. Byrne, both of Los Angeles, at Piedmont, Cal., August 6.

Arminus Blair Lyon, M.D., Ulster, Pa., to Miss Cecile M. Shumway of Sayre, Pa., August 14.

Hugh Augustine Riley, M.D., to Miss Clotilde L. Dunne, both of New York City, July 28.

Ralph Stephen Fisher, M.D., to Miss Hazel Therkelsen, both of Portland, Ore., August 9.

Deaths

John J. Mulheron, M.D. University of Michigan, Ann Arbor, 1869; and once president of the Wayne County Medical Society; a member of the Michigan State Medical Society; at one time owner and publisher of the *Chicago Medical Review;* in 1886 a member and president of the Detroit Common Council and president of the Wayne County Supervisors and a member and president of the Board of Estimates in 1888; died at his home in Detroit, August 2, aged 67.

William R. Mattox, M.D. Rush Medical College, 1888; formerly a member of the American Medical Association; once coroner of Vigo County, Wis.; for five years president of the Vigo County Medical Society and for the time president of the Union Hospital Board, Terre Haute: died at his home in that city, August 2, from nephritis, aged 58. A large delegation represented the Vigo Medical Association at the funeral.

William Basilio Mackie, M.D. Harvard Medical School, Boston, 1862; for half a century a practitioner of Boston and formerly on the staff U. S. Marine Hospital, Chelsea, the Boston City Dispensary and the Boston City Hospital; a member of the Massachusetts Medical Society; vice-consul of Venezuela at Boston: died at the home of his son in Brookline, August 8, aged 79.

Albert Steuben Hotaling, M.D. College of Physicians and Surgeons, Baltimore, 1894; a fellow of the American Medical Association; professor of obstetrics in the Syracuse University College of Medicine; one of the most prominent practitioners of Syracuse; died at the Hospital for Women and Children in that city, August 8, a day after an operation for appendicitis, aged 40.

Clinton Clarence Miller, M.D. New York University, New York City, 1877; for five years acting assistant surgeon in the Army with station at Fort Sisseton, N. D.; a resident of St. Paul since 1856; for many years a member of the staff of the City Hospital and physician to the City Workhouse; died at his home, August 12, from paralysis, aged 59.

S. Sollers Maynard, M.D. Jefferson Medical College, 1860; a fellow of the American Medical Association; for more than fifty years a practitioner of Maryland; once president of the Farmers and Mechanics' Bank; physician to the Montevue Hospital and city health officer; died in his office in Frederick, August 3, from angina pectoris, aged 78.

George Raynolds Stearns, M.D. New York Homeopathic Medical College, New York City, 1878; a member of the staff of the Buffalo Homeopathic Hospital and formerly medical director of the Ingleside Home; was struck by a street car while crossing a street in Buffalo August 8, and died a few hours later, aged 55.

Eugene Carson Hay, M.D. University of Virginia, Charlottesville, 1890; a fellow of the American Medical Association, and a member of the Association of Military Surgeons of the United States; a pioneer resident of Hot Springs; died at his country home near that city, August 6, after a long illness, aged 48.

Calvin Ingram Fletcher, M.D. Medical College of Indiana, Indianapolis, 1880; a fellow of the American Medical Association, and a well-known physician of Indianapolis, while exploring a crevasse in Blackfoot glacier, Glacier Park, Mont., August 19, fell over a 600-foot precipice, and was instantly killed.

C. C. Garrett, M.D. Atlanta (Ga.) Medical College, 1872; for twenty-four years a member of the Douglas County (Ga.) Board of Education and for sixteen years of that time, chairman; mayor or councilman of Lithia Springs since the incorporation of the town; died at his home, August 5, aged 63.

Philip Scholz, M.D. St. Louis College of Physicians and Surgeons, 1889; a fellow of the American Medical Association; a pioneer druggist and physician of St. Louis; who was struck by an automobile while alighting from a car, July 27; died at St. Mary's Infirmary, St. Louis, July 31, aged 72.

Thomas William Bailey, M.D. University of Pennsylvania, Philadelphia, 1902; a member of the Medical Society of the State of Pennsylvania; of Philadelphia; for many years consulting surgeon to St. Agnes Hospital; died in that institution, August 1, from typhoid fever, aged 34.

Oliver Livingston Jones, M.D. Bellevue Hospital Medical College, 1871; a retired practitioner of New York City; died in the Polyclinic Hospital, New York City, August 9, from the effects of bullet wounds of the head, self-inflicted it is believed with suicidal intent, aged 63.

Ovid Allen Hyde, M.D. Eclectic Medical College of the City of New York, 1884; for twenty-one years a member of the faculty of his alma mater and consulting surgeon on the dispensary staff of the college; died at his home in Queens, Long Island, August 5, aged 61.

Lemuel Austin Ferry, M.D. University of Georgetown, Washington, D. C., 1879; formerly a member of the American Medical Association; a member of the Illinois State Medical Society; died at his home in Geneseo, June 14, from heart disease, aged 69.

John Bohl, M.D. Cincinnati College of Medicine and Surgery, 1859; a member of the Ohio State Medical Association and one of the organizers of the Washington County Medical Society; died at his home in Watertown, August 13, from senile debility, aged 84.

Stephen Charles De Veny, M.D. University of Pennsylvania, Philadelphia, 1871; a member of the Illinois State Medical Society and a resident of Chicago for more than forty years; died at his home in that city, August 16, from nephritis, aged 68.

Adin Wilson Mitchell, M.D. Cincinnati College of Medicine and Surgery, 1880; a member of the Ohio State Medical Association; physician to the Brown County Children's Home; died at his home in Georgetown, O., May 24, aged 65.

James Thacker Boutelle, M.D. Harvard Medical School, 1871; a member of the Medical Society of Virginia; health officer of Elizabeth City County; died at his home in Hampdon, August 7, from a nervous breakdown, aged 68.

Francis Xavier Dooley, M.D. Georgetown University, Washington, D. C., 1865; a member of the Medical Society of the District of Columbia, and also a druggist; died at his home in Washington, August 10, aged 72.

Robert T. Shaw, M.D. Jefferson Medical College, 1877; of Denver; formerly a member of the Colorado Legislature and a graduate in theology; died in St. Luke's Hospital, Denver, August 5, from uremia, aged 59.

William Frederick Beyer, M.D. University of Michigan, Ann Arbor, 1912; of Detroit; died in Harper Hospital, July 22, from septicemia, contracted while an intern in the University Hospital, Ann Arbor, aged 24.

Henry Skelton Carter, M.D. College of Physicians and Surgeons, New York City, 1872; a practitioner of New York City; died suddenly at his home in Tarrytown, N. Y., July 2, from angina pectoris, aged 64.

Edward Munroe Lane, M.D. Bellevue Hospital Medical College, 1892; of Pawtucket, R. I.; died in the Rhode Island Hospital, Providence, July 31, after an operation for disease of the intestine, aged 46.

Alexander A. Staats, M.D. Cincinnati College of Medicine and Surgery, 1868; a member of the Ohio State Medical Association; died at his home in Summerfield, May 16, from heart disease, aged 70.

Tence Francis Massey, M.D. Eclectic Medical Institute, Cincinnati, 1866; also a druggist; of Medaryville, Ind.; died in St. Elizabeth's Hospital, Lafayette, Ind., July 11, from septicemia, aged 73.

Bernard Francis Dennis, M.D. University of Buffalo, N. Y., 1899; of Buffalo; a fellow of the American Medical Association; died in a hospital in Oil City, Pa., about August 1, aged 36.

Elie-Jean B. Hazzard, M.D. Eclectic Medical College of the City of New York, 1886; also an attorney; died at his home in Lawrence, Kan., from atrophic cirrhosis of the liver, aged 72.

Henry M. Swigert, M.D. Cincinnati College of Medicine and Surgery, 1880; a veteran of the Civil War; died at his home in Hastings, Neb., August 5, from cerebral hemorrhage, aged 66.

Charles A. Sweet, M.D. College of Physicians and Surgeons of Chicago, 1887; a member of the Michigan State Medical Society; died at his home in East Jordan, May 4, aged 53.

James Pendleton Carter, M.D. University of Maryland, Baltimore, 1852; for 35 years a practitioner of Berkeley County, W. Va.; died at his home in Gerrardstown, August 4, aged 83.

James E. Overstreet, M.D. Southern Medical College, Macon, Ga., 1893; formerly mayor of Baxley, Ga., and president of the Citizens' Banking Association; died at his home, August 3.

Clarence Benjamin Wilson, M.D. University of Michigan, Ann Arbor, 1890; a member of the Vermont State Medical Society; died at his home in Bradford, May 31, aged 47.

Harry Daniel Abbott, M.D. Tufts College Medical School, Boston, 1904; a fellow of the American Medical Association; died at his home in Danvers, Mass., July 16, aged 33.

Andrew J. Shrader (license, Ohio); also an attorney; for many years a practitioner of Columbus; died in Milton Center, O., June 19, from senile debility, aged 93.

George Elbridge Swan, M.D. New York Homeopathic Medical College, 1866; in 1881, mayor of Beaver Dam, Wis.; died at his home in that place August 10, aged 75.

George W. Cornish, M.D. Detroit College of Medicine, 1894; a member of the Michigan State Medical Society; died at his home in Lawton, August 8, aged 53.

Hiram S. Broiles, M.D. University of Nashville, Tenn., 1873; for two terms mayor of Fort Worth, Tex.; died at Fort Leavenworth, Kan., August 7, aged 68.

Charles Owen Patton, M.D. Bellevue Hospital Medical College, 1886; died at his home in McFall, Mo., August 1, aged 58.

R. L. Rylee, M.D. Georgia College of Eclectic Medicine and Surgery, Atlanta, 1891; died at his home in Bogart, July 25.

Samantha Smith (license, Mo., 1883); of Kansas City, Kan.; died in State Hospital No. 2, St. Joseph, Mo., July 27.

Silas H. Cardwell (license, Arkansas, 1903) died at his home in Hot Springs, August 1, aged 74.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

LEMMON'S RHEUMATISM CURE

Secretary of a Coal Company Offers to Instruct Physicians—Price One Dollar

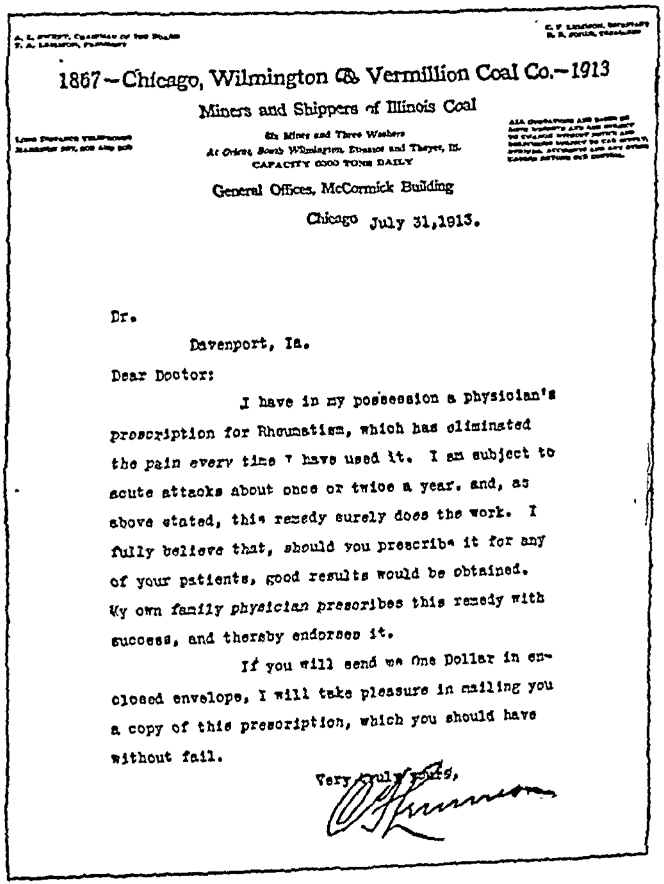
On August 4 and 5 the Propaganda for Reform department received an extraordinarily heavy mail. In addition to the usual batch of inquiries regarding quacks and nostrums about seventy letters were received from Iowa physicians. Most of these letters enclosed a typewritten letter on the stationery of the Chicago, Wilmington and Vermillion Coal Company, signed by the secretary of that company, C. F. Lemmon. Mr. Lemmon's letter to the physicians of Iowa ran thus:

> *"Dear Doctor:* I have in my possession a physician's prescription for Rheumatism, which has eliminated the pain every time I have used it. I am subject to acute attacks about once or twice a year, and, as above stated, this remedy surely does the work. I fully believe that, should you prescribe it for any of your patients, good results would be obtained. My own family physician prescribes this remedy with success, and thereby endorses it.
>
> "If you will send me One Dollar in enclosed envelope, I will take pleasure in mailing you a copy of this prescription, which you should have without fail."

The physicians of the Hawkeye state are evidently poor game for the hunter of "suckers." Some of their comments on Mr. Lemmon's letter are worth quoting:

"I didn't bite. What is the graft?"

"What kind of a graft is this fellow trying to work?"



1867—Chicago, Wilmington & Vermillion Coal Co.—1913

Miners and Shippers of Illinois Coal

Six Mines and Three Washers

General Offices, McCormick Building

Chicago July 31,1913.

Dr.

Davenport, Ia.

Dear Doctor:

I have in my possession a physician's prescription for Rheumatism, which has eliminated the pain every time I have used it. I am subject to acute attacks about once or twice a year, and, as above stated, this remedy surely does the work. I fully believe that, should you prescribe it for any of your patients, good results would be obtained. My own family physician prescribes this remedy with success, and thereby endorses it.

If you will send me One Dollar in enclosed envelope, I will take pleasure in mailing you a copy of this prescription, which you should have without fail.

Very truly yours,

Photographic facsimile of the letter sent by Mr. Lemmon to the physicians of Iowa offering to sell a prescription for rheumatism. The name of the recipient of this letter was deleted before photographing it.

"I notice his name is Lemmon. I wonder if he is trying to hand me one."

"The secretary of this firm certainly must think physicians are an easy mark."

"It surely is a unique sideline for a coal company."

And so on. As it seemed probable that Mr. Lemmon would extend his Get-Rich-Quick Wallingford operations, it seemed worth while to head off his "game." THE JOURNAL accordingly asked some of the Iowa physicians who had been favored with Mr. Lemmon's invitation to send the secretary of the Chicago, Wilmington and Vermillion Coal Company the dollar necessary to obtain the prescription. This was done, but alas, the medical profession is to be kept in the dark regarding this marvelous remedy, for the money orders sent to Lemmon were returned to the senders with a short note to this effect:

> "Yours enclosing $1.00 for rheumatism prescription received. Am obliged to return same to you for the reason that it now appears to me that I cannot fairly do as proposed."

This note, it should be said, while a typewritten one and signed by Mr. Lemmon, was not on the stationery of the coal company. It was on a plain sheet of paper.

What brought about Mr. Lemmon's change of heart in this matter we do not know. It is barely possible that the president of the Chicago, Wilmington and Vermillion Coal Company, who is Mr. C. F. Lemmon's father, may have found that his company was receiving an amount of notoriety that was not healthy for a legitimate business.

Correspondence

Cerebrospinal Fluid in Brain Tumors

To the Editor:—In THE JOURNAL of July 26, 1913, p. 265, Dr. M. J. Karpas states that "in tumor of the brain of non-luetic genesis the fluid is free from pathologic findings." I may say without going into the literature for quotations that a number of cases of non-luetic brain tumors have been reported in which the spinal fluid showed a positive result from Noguchi's modification of the Wassermann test and increased cell-count. I have had two such cases myself. In one of these cases in which I had originally made a diagnosis of brain tumor I revised the same to cerebrosyphilis on the basis of the laboratory report. The necropsy showed non-specific tumor at the pontocerebellar angle. Therefore, that the spinal fluid may in cases of non-specific brain tumor show increased cell-count and positive Noguchi test appears to me as a matter of very considerable clinical importance.

THEODORE DILLER, M.D., Pittsburgh, Pa.

[The foregoing letter was referred to Dr. Karpas, who replies:]

As a general rule, the cerebrospinal fluid in brain tumors of a non-syphilitic etiology is usually free from abnormal constituents. However, in cases in which the fluid shows an increase of albumin or lymphocytosis, one must think of two possible conditions: (1) a syphilitic factor in addition to the neoplasm, and (2) the production of some irritation which may result from the tumor growth coming into close contact with the meninges, causing the pathologic phenomena of the cerebrospinal fluid. Tumors in the cerebellopontine angle may cause sufficient irritation of the meninges to account for the increase of cells and globulin content. In my experience with brain tumors, I have found no pathologic conditions of the cerebrospinal fluid. Dr. Diller's suggestions are worthy of attention—indeed, our knowledge of the cerebrospinal fluid in tumors is not at all exhausted. The more records of careful fluid examinations of cases of brain tumors with necropsies and operations, the more light will be shed on this vital question.

MORRIS J. KARPAS, M.D., New York.

Data Requested on Great Artists and Famous Anatomists

To the Editor:—For several years I have been trying to secure material for a monograph on great artists and famous anatomists. Will you kindly print this letter, in the hope that some of your readers may give me data concerning this interesting subject?

JAMES MOORES BALL, M.D., 4500 Olive St., St. Louis.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

THE NEW CANADIAN MEDICAL PRACTICE ACT

To the Editor:—What are the qualifications for practicing in Alberta or Saskatchewan? Is the new Canadian medical practice act now in operation and does it apply to all parts of the Dominion? What is the act? CANADIAN.

ANSWER.—The Medical Council of Alberta admits to its register any one who presents a certificate from the registrar of the University of Alberta, showing that the holder is duly qualified. A standard high-school education and a four years' course in a recognized medical college are required for those graduating prior to June 1, 1913. For those graduating after that date the preliminary education required must be equivalent to matriculation in the University of Alberta, and the applicant must have completed a five-year medical course, including the preliminary year in physics, chemistry and biology. For osteopaths the preliminary requirements and the examination in all the common subjects are the same as for physicians. Examinations are written and oral. The examination fee is $50; registration fee, $50; annual assessment, $2. The registrar of the Council is Dr. G. Macdonald, Calgary, Alberta.

In Saskatchewan the requirements are practically the same as in Alberta. The registrar of the Medical Council is Dr. G. A. Charlton, Regina, Saskatchewan.

The new Canadian practice act is now in effect and the register of the Medical Council of Canada was opened July 1 of this year. The act provides that any person already licensed in any of the provinces who has been in practice for ten years may register under certain conditions. Those licensed less than ten years may register when the ten-year period has been completed. Other candidates may, if otherwise qualified, take the examination of the Medical Council of Canada, the passing of which will entitle them to practice medicine in any part of the Dominion. The first Dominion examination will be held in Montreal, October 7 of this year.

INCONSISTENT PRESCRIPTION

To the Editor:—Please comment on the enclosed prescription as to compatibility and physiologic effects of the different ingredients.

K. I.	ʒ ii
Hydrarg. chlor.	gr. i
Tr. gelsemium.	ʒ i
Tr. aconite	m. xvi
Strych. sulph.	gr. ⅓
Chloral hydrate	ʒ iii
Liq. pot. ars.	ʒ i
Syr. *tolu*	
Aq. mentha pip. āā qs	℥ ii

M. Sig.: ʒ i in aq q 3 hrs.

G. S. C.

ANSWER.—Such a prescription affords opportunity for much criticism. The presence of nine ingredients marks it at once as a *specimen of disgraceful* polypharmacy. There are many evident inconsistencies. The mixture of potassium iodid and mercuric chlorid forms a reagent for alkaloids which would probably precipitate the strychnin and might give rise to fatal poisoning. Perhaps the chloral hydrate is added as an antidote to possible strychnin poisoning. There is no reason for combining together such opposite agents as strychnin and tincture of aconite or tincture of gelsemium.

THEORY OF OSTEOPATHY AND CHIROPRACTIC

To the Editor:—I wish to inform myself thoroughly in regard to the actual theory and therapeutics of osteopathy and of chiropractic, so as to meet, intelligently, arguments made in favor of these cults by my patients. E. A. H., California.

ANSWER.—The following books and articles may be referred to:

OSTEOPATHY

Barber: Osteopathy, Janish, Kirksville, Mo., price $3.
Burns: Basic Principles of Osteopathy, Louisa Burns, Los Angeles, price $4.50.
Clark: Diseases of Women, A. S. O. Book Co., 602 W. Jefferson St., Kirksville, Mo., price $5.

LITERATURE ON COLEY'S TOXINS IN SARCOMA

To the Editor:—I wish to use Coley's toxin or Coley's antisarcoma serum in one of my cases. Will you please tell me where I can get it and how it should best be administered? I can find nothing definite concerning it in any literature that I have. A loan of any articles, reprints or magazines written in English would be appreciated and the literature will be promptly and carefully returned. J. E. SNYDER, M.D., Cooperstown, Ill.

ANSWER.—Erysipelas and prodigiosus toxins (Coley). Prepared by Parke, Davis & Co., Detroit, Mich. The preparation is described in N. N. R., 1913, page 236.

The toxins are injected in gradually increasing doses, at first in a part of the body removed from the tumor and later, if possible, into the tumor itself.

The following articles have appeared on this subject:

Hunt, E. R.: Case of Recurrent Carcinoma of Parotid Gland Treated with Coley's Fluid, *Lancet*, London, June 17, 1911; abstr., THE JOURNAL, July 15, 1911, p. 252.

CASE OF AMNIOTIC ADHESION

To the Editor:—Recently I had an obstetric case in which the head of the child was adherent to the placenta and the uterine wall. Are there reports of similar cases? What books or papers can I consult on the subject? R. VORSANGER, M.D., Chicago.

ANSWER.—Ballantyne's "Antenatal Pathology and Hygiene," ii, contains a full description of amniotic adhesions. Frequently the amniotic bands pass from the fetal side of the placenta to the head and so it appears that the head is adherent to the placenta. In these cases there are generally other malformations present. Such cases as reported should be described in detail and pictures taken of them. Then they might be of value in determining some of the problems of teratogenesis, that is, the origin of monsters.

POTASSIUM PERMANGANATE SOLUTION

To the Editor:—1. How much potassium permanganate is required to make a quart of 1:2,000 and 1:5,000 solutions? How is the amount of potassium permanganate determined in order to make any amount and of any strength of solution?

2. What health resorts are best for patients afflicted with kidney and liver diseases?

3. (*a*) How long after rupture of hymen can the carunculae myrtiformes be seen? (*b*) Is it possible to state with any degree of accuracy how long the hymen has been ruptured by presence or absence of carunculae myrtiformes? SUBSCRIBER.

ANSWER.—1. For a quart of a solution of 1:2,000 use 7½ grains, and for a quart solution of 1:5,000 use 3 grains. One quart is equivalent to 14,600 grains, so that 15 grains to the quart equals approximately 1:1,000.

2. Those with a mild equable climate.

3. (*a*) The carunculae myrtiformes are the results of labor and not of the rupture of the hymen. (*b*) No.

THE CAUSE OF "PINK-EYE"

To the Editor:—Kindly inform me whether the germ which causes "pink-eye" has been demonstrated, and if so, what it is. E. HOCHHEIMER, M.D., New York.

ANSWER.—"Pink-eye" is a popular term applied to an acute contagious conjunctivitis which is due to an organism first described in 1883 by Robert Koch and later by Weeks and hence called the Koch-Weeks bacillus. It is a very small organism, difficult to cultivate. Cultures of it reproduce the disease when placed on the human conjunctiva.

REMOVAL OF SILVER AND IODIN STAINS FROM FINGERS

To the Editor:—Often the fingers are accidentally stained by nitrate of silver, by tincture of iodin and by bacterial stains, much to the annoyance of the physician. Silver stains, recent or old, are effectually removed by tincture of iodin. Stains from the latter drug are immediately removed by aqua ammoniae. Many of the bacterial stains, as Loeffler's blue, gentian violet and carbol fuchsin are decolorized by acid alcohol.
P. G. SKILLERN, JR., M.D., Philadelphia.

ANSWER.—A solution of sodium thiosulphate is better than ammonia-water to remove iodin stains.

MEMBRANOUS CROUP AND LARYNGEAL DIPHTHERIA

To the Editor:—1. What is the [illegible] opinion as to the identity of membranous croup and [illegible]? 2. Is a membranous laryngitis always diphtheritic? C. G. H., Arkansas.

ANSWER.—1. They are usually regarded as identical. 2. No. About one-seventh of the cases are due to other organisms, chiefly streptococci.

ANSTIE'S LIMIT IN ALCOHOLISM

To the Editor:—Please tell me what is understood as Anstie's limit in alcoholism. I meet the term in life insurance and cannot find it explained anywhere.
S. C. BROADSTREET, M.D., Mt. Pleasant, Texas.

ANSWER.—Anstie's limit is the amount of alcohol oxidized per day by the normal organism, and it is put at 1½ ounces.

RED CROSS INSIGNIA AND THE SPEED LIMIT

To the Editor:—Can the city authorities lawfully hold up a doctor's car, carrying a red cross, and fine the owner for exceeding the speed limit? G. A. Z.

ANSWER.—Yes.

The Influence of Mucomembranous Colitis on Health.—Mucomembranous colitis is not a disease that directly destroys life, but it kills health and happiness. Patients who suffer from it and go unhealed are apt to drift into a state of chronic invalidism, never really well, spending most of their time on the sofa, and with all their thoughts, as some one has said, revolving round the umbilicus—a condition which is sometimes worse than death.—Robert Hutchison in *Clinical Journal.*

MODEL BILL FOR THE CONTROL OF OPHTHALMIA NEONATORUM

The Committee on Prevention of Blindness, one of the subcommittees of the Council on Health and Public Instruction, was originally organized as a Committee on Ophthalmia Neonatorum. Efforts to control this dreadful disease have always been prominently in the minds of the members of this Committee, which, in conjunction with the Medico-Legal Bureau of the Council, has prepared a preliminary draft of a model bill on this subject, the text of which appears below. This bill will be widely distributed for criticism, revised and redrafted in the light of the criticisms and suggestions received, in the hope of evolving a bill which may be endorsed as a standard by the American Medical Association and other bodies interested in public health. It should be clearly understood that this is the first draft of this measure and that criticisms are not only expected, but are earnestly desired.

A BILL FOR AN ACT ENTITLED AN ACT FOR THE PREVENTION OF BLINDNESS FROM OPHTHALMIA NEONATORUM; DEFINING OPHTHALMIA NEONATORUM; DESIGNATING CERTAIN POWERS AND DUTIES AND OTHERWISE PROVIDING FOR THE ENFORCEMENT OF THIS ACT

Section 1. Ophthalmia Neonatorum Defined.—Any condition of the eye, or eyes, of any infant shall, independent of the nature of the infection, be known as ophthalmia neonatorum, in which there is any inflammation, swelling or redness, in either one, or both eyes of any such infant, either apart from, or together with, any unnatural discharge from the eye, or eyes, of any such infant at any time within two weeks after the birth of such infant.

Section 2. Duties of Physicians, Midwives, Etc.—It shall be the duty of any physician, surgeon, obstetrician, midwife, nurse, maternity home, or hospital of any nature, parent, relative, and any person or persons attendant on, or assisting in any way, whatsoever, any woman at childbirth, or attendant on, or assisting in any way, whatsoever, any infant, or the mother of any infant, at any time within two weeks after childbirth, knowing the condition, hereinabove defined, to exist, and within six hours thereafter, to report such fact, as the State Board of Health shall direct, to the local health officer of the city, town, village, or whatever other political division there may be, within which the mother of any such infant may reside.

Section 3. Duties of the Local Health Officer.—It shall be the duty of the local health officer:

1. To investigate each case as filed with him in pursuance with the law, and any other such case as may come to his attention.

2. To report all cases of ophthalmia neonatorum, and the result of all such investigations as he shall make, as the State Board of Health shall direct.

3. To conform to such other rules and regulations as the State Board of Health shall promulgate for his further guidance.

Section 4. Duties of the State Board of Health.—It shall be the duty of the State Board of Health:

1. To enforce the provisions of this act.

2. To promulgate such rules and regulations as shall, under this act, be necessary for the purpose of this act, and such as the State Board of Health may deem necessary for the further and proper guidance of local health officers, etc.

3. To provide for the gratuitous distribution of a scientific prophylactic for ophthalmia neonatorum, together with proper directions for the use and administration thereof, to all physicians, midwives, and the like, as may be engaged in the practice of obstetrics, or assisting at childbirth.

4. To furnish prompt and gratuitous treatment to any infant infected with ophthalmia neonatorum, and to the mother of such infant as well; provided that gratuitous treatment shall not be furnished either to any infant, so infected, nor to its mother, should either, or both, such infant and its mother be under the care of a regularly qualified physician; provided further that the State Board of Health shall defray the expense of such treatment out of such sum as may be appropriated for its use.

5. To print and publish such further advice and information concerning the dangers of ophthalmia neonatorum, and the necessity for prompt and effective treatment thereof, as may be deemed fit.

6. To furnish copies of this law to all physicians, midwives, and the like, as may be engaged in the practice of obstetrics, or assisting at childbirth.

7. To keep a proper record of any and all cases of ophthalmia neonatorum, as shall be filed in their office in pursuance with this law, and as may come to their attention in any way, and to constitute such records a part of the annual report to the governor and the legislature.

8. To report any and all violations of this act as may come to their attention, to the prosecuting attorney of the district wherein said misdemeanor may have been committed, and to assist said official in any way possible, such as by securing necessary evidence, etc.

Section 5. Duties of Maternity Homes, Etc., Physicians, Etc.—It shall be the duty of all maternity homes, and any and all hospitals, etc., to maintain such records of cases of ophthalmia neonatorum as the State Board of Health shall direct. It shall be the duty of any and all maternity homes, hospitals, public and charitable institutions, midwives and the like, in addition to reporting as hereinbefore enacted, to advise, prescribe and employ, in the treatment of all cases of ophthalmia neonatorum, such prophylactic as the State Board of Health shall direct.

Section 6.—Violation of Act a Misdemeanor; Knowledge.—The failure of any and all physicians, midwives, etc., as hereinabove set forth, to report as herein prescribed, or the failure of any hospital to record, as hereinbefore enacted, or the failure of any midwife, and the like, to treat as the State Board of Health shall have directed, any and all cases of ophthalmia neonatorum, as herein prescribed, and, under such circumstances as are herewith set forth, or any or all of such violations, as the case may be, shall constitute a misdemeanor under this act, shall, on a conviction thereof, be fined, for a first offense, not to exceed $50; for a second offense, not to exceed $100, and for a third offense, and thereafter, not to exceed $200 for each violation, and, if the accused be a midwife or the like, such person shall, in the discretion of the court, suffer a revocation of license, or both fine and revocation, as the court may see fit, and if the accused be a maternity home, or the like, duly incorporated under the laws of the state, the court may, in its discretion, order a revocation of its charter; and any collusion between any official and any person, or between any others herein named, to misstate or conceal any facts which, under this act, it is essential to report correctly, shall like wise constitute a misdemeanor, and the accused shall, on a conviction, suffer a penalty such as is hereinabove enacted. The act of the agent in the scope of his employment shall be deemed the act of the principle. (Any, and all, cases of ophthalmia neonatorum, or the resultant blindness therefrom, on which the accused may have been in attendance, as hereinabove set forth, and of which no proper record has been made as herein enacted, shall be taken as *prima facie* evidence of the infection and of the intent on the part of the accused to neglect to make a proper record of such case.) It shall be the duty of the state's attorney, for the proper district, to prosecute for all misdemeanors as herein prescribed.

Section 7. Appropriation.—The sum of $———— shall be annually appropriated for the use of the State Board of

Health in enforcing and carrying out the provisions of this act. Any and all necessary and legitimate expenses that may be incurred in prosecuting a case under this act, shall, on proper showing, be met by the State Board of Health out of this appropriation. In addition thereto, all fines and penalties recovered hereunder, shall be paid into the state treasury and shall constitute a special fund for the uses and purposes of the State Board of Health as herein enacted.

SECTION 8. Emergency.—An emergency existing, this act shall take effect on its passage, as by law prescribed.

SECTION 9.—Repealing.—All acts and parts of acts, in conflict herewith are hereby repealed.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

MASSACHUSETTS: State House, Boston, September 9-11. Sec., Dr. Walter P. Bowers, Room 159, State House.

MISSOURI: Coates House, Kansas City, September 2-4. Sec., Dr. J. A. B. Adcock, State House, Jefferson City.

NEW YORK: September 23-26. Chief of Examinations Division, Mr. Harlan H. Horner, Department of Education, Albany.

Ohio April and July Reciprocity Reports

Dr. George H. Matson, secretary of the Ohio State Medical Board reports that at the meetings held April 15 and July 1, 1913, 32 candidates were licensed through reciprocity. The following colleges were represented:

LICENSED THROUGH RECIPROCITY APRIL 15, 1913.

College	Year Grad.	Reciprocity with
Howard University, Washington	(1912)	W. Virginia
College of Physicians and Surgeons, Chicago	(1905)	Indiana
Rush Medical College	(1912)	Minnesota
Kansas Medical College	(1905)	Kansas
College of Physicians and Surgeons, Baltimore (1910) (1911)		W. Virginia
University of Maryland	(1912)	Maryland
University of Michigan, Department of Medicine and Surgery (1905) (1909) (1911)	(1912)	Michigan
University of Michigan, Homeopathic College	(1912)	Michigan
Eclectic Medical Institute, Cincinnati	(1909)	Arkansas
University of Pennsylvania	(1909)	Penna.
University of Pittsburgh	(1911)	Michigan
Western University of Pennsylvania	(1901)	Penna.
Jefferson Medical College	(1908)	Penna.

LICENSED THROUGH RECIPROCITY JULY 1, 1913

College	Year Grad.	Reciprocity with
Georgetown University	(1911)	Dist. Colum.
Indiana Medical College	(1906)	Indiana
Baltimore Medical College	(1902)	W. Virginia
College of Physicians and Surgeons, Baltimore	(1911)	Maryland
University of Maryland	(1904)	Maryland
Maryland Medical College	(1903)	Penna.
University of Michigan, Department of Medicine and Surgery (1903) (1910)	(1912)	Michigan
Barnes Medical College	(1904)	Missouri
Cleveland Homeopathic Medical College	(1904)	Penna.
Jefferson Medical College	(1912)	Penna.
University of Pennsylvania	(1912)	Penna.
Jefferson Medical College (1912) Penna.;	(1912)	New Jersey
Medico-Chirurgical College of Philadelphia	(1909)	Penna.

Delaware June Report

Dr. Henry W. Briggs, secretary of the Medical Council of Delaware, reports the written examination held at Dover, Delaware, June 17-19, 1913. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 6, all of whom passed. Four candidates were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Jefferson Medical College (1912) 85.4, 91.5;	(1913)	81.8, 82.3, 83.7.
University of Pennsylvania	(1913)	80.7

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
University of Maryland	(1911)	District of Columbia
University of Pennsylvania (1900) Maryland	(1910)	Penn.
Hahnemann Medical College of Philadelphia	(1883)	Penn.

Kentucky June Report

Dr. J. N. McCormack, secretary of the Kentucky State Board of Health, reports the written examination, held at Louisville, June 3-5, 1913. The number of subjects examined in was 15; percentage required to pass, 70, and not less than 60 in any one branch. The total number of candidates examined was 62 of whom 54 passed, including 3 osteopaths, and 8 failed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Chicago College of Medicine and Surgery	(1913)	89
Hering Medical College (1912) 86;	(1913)	87, 89
University of Louisville (1910) 72; (1912) 75, 77;	(1913)	70, 76, 77, 79, 79, 79, 80, 80, 80, 81, 82, 83, 83, 83, 83, 84, 84, 84, 85, 85, 85, 85, 85, 86, 86, 86, 86, 86, 87, 87, 87, 88, 89, 91
Johns Hopkins University (1911) 88; (1912) 85;	(1913)	84, 86
Ohio-Miami Medical College	(1913)	87
Meharry Medical College	(1913)	77
Vanderbilt University (1912) 83;	(1913)	82, 84, 85

FAILED

College	Year Grad.	Per Cent.
Bennett Medical College	(1913)	57
University of Louisville (1909) 42; (1911) 55;	(1912)	66

Book Notices

EINFÜHRUNG IN DIE HÖHERE MATHEMATIK FÜR NATURFORSCHER UND AERZTE. Von Dr. J. Salpeter. Price, 12 marks. Paper. Pp. 336 with 147 illustrations. Jena: Gustav Fischer, 1913.

This work is essentially a text-book for beginners in the differential and integral calculus. It differs from the current text-books of that subject intended for students of mathematics chiefly in the greater number of applications of the mathematical results to problems of physics, chemistry and allied sciences. In this respect it is decidedly an interesting work. During the past few decades a marked tendency has been generally noticeable on the part of writers in this field to seek to enhance the interest of the abstract theory by illustrative examples showing how the theory can be applied under diverse concrete conditions. The great obstacle in the way has been the fact that such illustrations are really illuminating only to one who is well acquainted with the field in which the application is made, and that there exists only a limited number of concrete situations in natural sciences which are so simple that they can readily be made intelligible to the average reader who has no technical knowledge of the sciences in question, and which at the same time lead to mathematical formulations sufficiently complex to constitute effective illustrations for the various divisions of so extensive a subject as the calculus. Salpeter has succeeded in getting together possibly an unprecedentedly large number of such illustrations, and for this reason his work will prove interesting and helpful to those who have already made some study of the calculus, as well as to beginners. However, it is quite possible that the beginner might find himself distracted rather than helped in his first study of the basic principles of the calculus by an attempt to form an image of so large a number of concrete and more or less unfamiliar physical situations. To the physician, in the most restricted sense of the word, the book brings no message; its appeal is rather to him as physicist, physiologist, chemist or man of general culture.

SKIN-GRAFTING FOR SURGEONS AND GENERAL PRACTITIONERS. By Leonard Freeman, B.S., M.A., M.D., Professor of Surgery in the Medical Department of the University of Colorado. Cloth. Price, $1.50. Pp. 139, with 24 illustrations. St. Louis: C. V. Mosby Company, 1912.

This little monograph presents in a concise manner the general subject of skin-grafting. The various methods of grafting, the advantages and disadvantages of each, and the particular conditions under which each is most applicable, are well outlined. The grafting of animal membranes of various kinds to the human body is described and the results thus far obtained detailed. Experiments as well as practical experience show unmistakably the advantages of autografts over all other methods. It is an instructive and interesting little volume.

MALINGERING AND FEIGNED SICKNESS. By Sir John Collie, M.D., J.P., Medical Examiner, London County Council. Assisted by Arthur H. Spicer, M.B., B.S., D.P.H. Cloth. Price, $3 net. Pp. 340, with 44 illustrations. New York: Longmans, Green & Co., 1913.

Malingering is a condition that many physicians in their daily practice fail to take into consideration. Even those who frequently come in contact with cases of injury due to accident for which compensation or indemnity may be claimed often fail entirely to recognize malingering, even when it is present in some of its most common forms. Since workmen's compensation acts and accident indemnity insurance are becoming more common, it is necessary for physicians to pay more attention to this subject in order that justice may be done both parties. There are many forms of malingering and some of those practicing it are very clever, so that it takes an exceedingly keen diagnostician to detect the fraud. This little volume is not only timely, but it is also interestingly written. The author has had an unusually large experience in this line of work and exhibits a shrewdness in making deductions which shows great familiarity with the arts of the malingerer and deep insight into human nature. There is not only conscious malingering which is actually dishonest and malicious, but there is also unconscious malingering by honest persons. The physician should be able to recognize all forms wherever and whenever found. This book will be of great help to the physician who is called on to detect such cases.

ORGANIC AND FUNCTIONAL NERVOUS DISEASES. A Text-Book of Neurology. By M. Allen Starr, M.D., Ph.D., L.L.D., Professor of Neurology, College of Physicians and Surgeons, New York. Fourth Edition. Cloth. Price, $6 net. Pp. 970 with 353 illustrations. Philadelphia: Lea & Febiger, 1913.

In Starr's standard text-book on nervous diseases the general practitioner almost always finds the desired information stated in a few terse paragraphs, while in some other works he may have to wade through irrelevant material before reaching a rather indefinite statement. The great secret of Starr's success is his direct and dogmatic style; in reading a page in his book one almost imagines that the author is lecturing to the reader. While no radical changes can be discovered in this the fourth edition of the work, yet here and there improvements are noted. Especially commendable is the author's attitude toward the discussion of the theories of the neuroses and psychoneuroses. For instance, though no disciple of Freud's views, he does not disdain to at least state them and make personal comment. Among many other valuable articles under the functional diseases, the one on psychasthenia is a masterpiece of condensation. The criticism made in a previous review that the author had become so fond of the organic nervous diseases that the functional disturbances were somewhat meagerly treated by him, must now be withdrawn. In this edition even the functional nervous diseases have received adequate consideration.

DIE LEBERKRANKHEITEN. Für Studierende und Aerzte. Von Dr. C. A. Ewald, Gen. Med. Rat, Professor ord. hon. an der Kgl. Friedrich-Wilhelm-Universität. Paper. Price, 10 marks. Pp. 275, with 44 illustrations. Leipsic: Georg Thieme, 1913.

This monograph is a little fuller than many of the text-book articles on diseases of the liver. It embodies the results of Ewald's forty years of experience as a physician, twenty-five of which have been passed at the Augusta Hospital in Berlin. It is this clinical experience that constitutes the best feature of the book. Many of the illustrations are from material from Ewald's own cases and are good. The discussion of questions of physiology and pathology can hardly be called very thorough, nor is there evidence of that exhaustive search of the literature that one might expect in a monograph of this kind. While the book is to be commended it is hardly of the same grade of excellence as the same author's earlier work on diseases of the stomach. Perhaps this is due to the fact that that work contained more of original observation. The subject also had at that time the charm of freshness and the author more of the vigor and positiveness of young manhood.

TREATMENT AFTER OPERATION. By William Turner, M.S., F.R.C.S., Senior Surgeon to the "Dreadnought" Seamen's Hospital, Greenwich, and E. Rock Carling, B.S., F.R.C.S., Surgeon to the "Dreadnought" Seamen's Hospital, Greenwich. With a Chapter on the Eye by L. V. Cargill, F.R.C.S., Senior Ophthalmic Surgeon, King's College Hospital. London Medical Publications. Cloth. Price, $3.75. Pp. 247, with 55 illustrations. New York: Oxford University Press, 1912.

This manual is intended by the authors to furnish practitioners, house surgeons, senior nurses and students with a guide for the after-treatment of operative cases. It is eminently practical; there is no waste of words, the text being a direct statement of the means found satisfactory in the practice of the authors. Many useful formulas are given, and all directions and descriptions are *explicit*. The authors are conservative as to the length of time to be *spent in bed* by patients who have undergone section of the abdominal wall, and advocate a longer period than is *generally considered* necessary in this country; but, if this be an error, it is on the safe side. The value of the work is *considerably* enhanced by the inclusion of a section devoted to the care of patients after *operations on the eye. This is written by* Cargill and is thoroughly modern and complete. Altogether we should say that *the authors have succeeded in producing* a book exceedingly useful to those for whom it was specially written, and *also well worth perusal by the surgeon.*

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

American Journal of Insanity, Baltimore

July, LXX, No. 1, pp. 1-279

1 Dissimilar Heredity in Mental Disease. A. J. Rosanoff, Kings Park, N. Y.
2 *Stastistic Studies in Syphilis with Wassermann Reaction and General Paralysis. F. S. Hammond, Trenton, N. J.
3 *Insanity and Race. H. M. Swift, Portland, Maine.
4 *Blood in Pellagra.* J. C. Bardin, Petersburg, Va.
5 *Prison Psychosis. A Pseudonym?* P. E. Bowers, Michigan City, Ind.
6 Pathologic Histology of Cortex in Psychoses. A. Alzheimer, Breslau.

2. Syphilis and Wassermann Reaction.—The entire population of the New Jersey State Hospital at Trenton, which is *representative of the rural type of general population of the* state, was examined by Hammond by means of the Wassermann syphilis reaction, in all 1,583 individuals being tested. Seventy of these were cases of general paralysis, and 1,513 were cases otherwise diagnosed. Of the cases not general paralysis, 1,472 reacted negatively and forty-one positively, *on which basis* there is a percentage of 2.7 latent lues in the total hospital population not paresis. Including cases of *general paralysis* about 7 per cent. of all individuals of both sexes examined, and about 10 per cent. of all males were found to be *infected with syphilis* as judged by the serum reaction.

These relatively *low figures*, as *compared* with those of some previous more *limited investigations* in institutions, Hammond believes are solely and wholly *accounted* for by the type of general population and rural environment from which the individuals examined originally came, and further, that in the difference of environment is found the explanation for the discrepancies in results among these previous investigations themselves. Hammond believes, furthermore, that this investigation, both in itself and by comparison with some of the more reliable previous figures, shows that the relative prevalence of syphilis in city and country is in general exactly two to one. A careful analysis of all data, including age, sex, color, nationality, civil condition and type of psychosis leads to the conclusion that syphilis among the insane is no more frequent in occurrence and differs in no particular in its distribution from that found in any general community; that in fact investigations as to the frequency of syphilis among the insane offers the most convenient method of accurately determining the figures for any corresponding general population, and it is for this reason that Hammond believes that the prevalence of lues in the entire general adult population of the state of New Jersey is 7 per cent.

Only one type of psychosis other than general paralysis (and cerebral lues) has been found to be definitely related to syphilis as cause and effect in either direction. This is the type of focal brain disorder which occurs in middle life as a result of vascular sclerosis. This group was found to constitute 16 per cent. of all the arteriosclerotic mental disorders among men and which, although not symptomatically differentiated from other similar focal brain diseases, has an entirely different etiology which may be demonstrated by biologic methods. In the field of general paralysis comparison of biologic, cytologic and chemical findings has pointed out that not only are the processes thus indicated usually found in association, but that there is at least as much evidence for the belief that all are dependent on one and the same mechanism, viz., the inflammatory process of the central organ, as for the conclusion reached by others that each is separate and independent. Hammond's experience in this series with the original Wassermann technic and that of the Noguchi modification has shown that with alcoholic extract antigen the Wassermann test gave a 5 per cent. error of deficiency, and the Noguchi test a 2 per cent. error of excess, and that reliable results are only to be obtained by the use of both methods in combination.

3. Insanity and Race.—Swift summarizes his study by *stating that insanity occurs with relatively greater frequency* among the population of foreign birth and parentage than among native stock, and from this last it *may be inferred* that, associated with the three great causes of insanity, heredity, alcohol and syphilis, there is operative in *America another* potent factor in thé overfilling of our public asylums, *namely*, immigration.

Annals of Surgery, Philadelphia

August, LVIII, No. 2, pp. 145-288

7 *Surgery of Pancreas. W. J. Mayo, Rochester, Minn.
8 *Pancreatic and Peripancreatic Lymphangitis. J. B. Deaver* and D. B. Pfeiffer, Philadelphia.
9 *Laryngectomy for Cancer. G. W. Crile, Cleveland.
10 Excision of Both Lobes of Thyroid for Cure of Exophthalmic Goiter. W. S. *Halsted*, Baltimore.
11 *Partial Occlusion of Thoracic and Abdominal Aortas by Bands of Fresh Aorta and of Fascia Lata. W. S. Halsted, Baltimore.
12 *Surgery of Pulmonary Artery. W. Meyer, New York.
13 Sarcoma of Chest Wall. F. B. Lund, Boston.
14 Acute Perforating Sigmoiditis in Children: Report of Two Cases. J. Ransohoff, Cincinnati.
15 Excision of Infarct in Acute Hematogenous Infections of Kidney. L. W. Hotchkiss, New York.
16 Technic of Nephrolithotomy, Pyelolithotomy and Ureterolithotomy. J. H. Gibbon, Philadelphia.
17 Rupture of Bladder: Report of Tthree Cases. G. Woolsey, New York.
18 Sarcoma of Stomach. C. L. Scudder, Boston.
19 Surgical Aspects of Purpura. J. F. Mitchell, Washington, D. C.
20 Aneurysm of *Internal Iliac*. A. MacLaren, *St. Paul*, Minn.

7. Surgery of Pancreas.—In 448 resections of the stomach for benign and malignant diseases up to Dec. 31, 1912 (W. J. and C. H. Mayo) the average mortality was 10 per cent. In about 8 per cent. of these cases the pancreas was injured and the average mortality was 11 per cent. In none of these operations, however, was the main pancreatic duct reached, usually only a superficial piece was removed from the surface at a point where the pancreas was adherent to the diseased stomach. The bleeding was usually free and best controlled by catgut on a curved needle. It was noted that in these cases the pancreas had a fibrous capsule, the result of the localized peritonitis.

In thirty-one splenectomies performed in the Mayos' clinic the tail of the pancreas was injured three times, owing to the fact that the tail passes with the splenic vessels well up into the hilum of the spleen. In one case half the pancreas was resected for tumor. The patient made a good recovery, and remains well. The tumor which had the external characteristics of a malignant growth, proved on section to be a benign thick-walled trabeculated cyst buried in sclerosed pancreatic tissue.

9. Laryngectomy for Cancer.—In Crile's twenty-seven laryngectomies there were two deaths, and these two were apparently the most promising cases of all. The prognosis in these cases seemed so favorable that he ventured to discard the full preliminary preparations. In one case he made no preliminary protective operation of any kind, and the patient died at the end of five weeks with mediastinal abscess. In the other case he made a preliminary gauze packing in the neck around the trachea, but did not perform a preliminary tracheotomy. In this case he brought the isolated upper end of the trachea forward to the skin and anchored it. The entire isolated portion necrosed, as did also a portion of the trachea beyond the isolated part. As a result pus was inhaled into the respiratory tract below the level of the sternum. The necropsy showed no pneumonia and no mediastinitis, but a septic tracheitis and bronchitis. Death was the result of local absorption, and of absorption from the trachea and from the bronchial mucosa.

This case demonstrated most conclusively the efficiency of the granulation barrier which is created by a preliminary iodoform packing. Crile is convinced that had he made a preliminary tracheotomy, or had he allowed the trachea to remain in its bed, the patient would surely have recovered.

In sixteen of these twenty-seven laryngectomies for cancer the laryngeal box was so choked with the growth that tracheotomy was required to prevent suffocation. Most of the patients gave a long history of hoarseness followed by gradual, though intermittent, obstruction to respiration. In two cases there was associated lues. One of these last two cases illustrates well the clinical difficulty of diagnosis. The lesion was first diagnosed correctly as luetic, and under a course of treatment the greater part of the growth disappeared. The residual growth, however, showed a progressive tendency, and was later diagnosed as cancer. Laryngectomy was performed and the patient is now alive and well, more than three years since his operation. The special lesson of this case is that cancer of the larynx, like cancer of the tongue, may follow local luetic lesions. There is danger, therefore, that the hope of a luetic cure may defer too long the laryngectomy which is the only chance for the cure of the cancer. As the lymphatics are involved in extrinsic cancer, a much wider dissection is required. Operation in cases of extrinsic cancer is but a palliative remedy, but even in such cases total laryngectomy is advised, because local recurrence comes more surely and more quickly if one cuts into the growth.

11. Partial Occlusion of Aorta by Fresh Tissue.—April 29, 1912, Halsted operated on two dogs, partially occluding the aorta of one of them with a spiral aortic band and of the other with a cuff cut from the same vessel. Strips of aorta were employed rather than of fascia lata, for example, because he hoped that the elastic tissue, in case it did not endure, might at least serve its purpose for a time sufficient to cure an aneurysm. At the end of two months one of the dogs was killed and the cuff which had been used in this experiment was apparently organized and had not stretched to any appreciable extent. Above the cuff the aortic pulse was forcible, but below the constriction it was very feeble, though countable and accompanied by a thrill. The other dog operated on at the same time and in the same manner, except that a spiral band of aorta instead of a cuff had been employed, died (cause of death unascertained) about three weeks after the operation. In this instance the aorta had been almost completely occluded by the spiral aortic strip. The welt-like band had not stretched and seemed to be organized. The aorta, on being split longitudinally, was seen to be greatly wrinkled and almost occluded at the site of the band. Sections of the specimens indicated that the elastic coats of the bands as well as of the included artery were intact.

During the winter of 1912-13 Halsted made about twenty-five similar experiments with encouraging results. He has learned, however, that whereas the spiral bands seem to be perfectly safe there is danger in the employment of the cuffs. In two instances of twelve or more experiments, one of the mattress sutures taken to hold the flaps of the cuffs together cut part way through the cuffs and thus, being brought in contact with the aortic wall, wore a minute hole in the vessel, through which the animal bled to death. Such an accident can hardly happen with the employment of the spiral strip, for not only is the strain on the stitches very slight when this form of band is used, but even if it were so great that a thread might cut through the spiral at any point, it could hardly be brought to bear on the aorta in such way as to wear into its wall. To each end of the band of fresh tissue a narrow tape is sewed to facilitate the manipulation of the transplant, which is wound twice about the aorta. When one or two stitches have been taken at one end to hold the contiguous edges of the spiral together at this point, the other end of the strip is pulled on until the aorta is occluded to a little more than the desired amount, and then two additional stitches are taken to maintain the constriction.

Within the past few weeks Halsted has examined the bands of aorta, fascia lata and chromicized submucosa which had been wound about the aorta last autumn and winter. In two instances in which considerable constriction of the aorta had been made about four months previously, kymographic tracings of the blood-pressure in the femoral and carotid arteries were made. There was no diminution in the femoral pressure, and on investigating the band it was found in each instance to have relaxed and to have been partially absorbed. In dogs operated on as long as seven months ago there was a considerable absorption of the band; and in one instance only a trace of it remained. One spiral band which had been applied so as to make almost total occlusion seven months before seemed microscopically to be well preserved, but it no longer restricted the aorta, the lumen of which was completely restored, and whose underlying wall was apparently normal.

22. "Family Clusters" in the Prevalence of Pulmonary Tuberculosis.—In reviewing the records of 1,300 admissions to the North Reading State Sanitarium in the three and a half years of this institution's existence the authors found therein an interesting study in data relating to the pedigrees of certain cases. They learned that in 134 distinct examples there occurred the incidence of at least three cases of pulmonary tuberculosis in a single family. These groups of infected people they have designated as "family clusters." A study of these family groups leads them to believe that the domiciliary distribution of tuberculosis may be due wholly or in part to the establishment of foci of infection following carelessness of individuals, usually adult open cases with the disease. The swiftest channels for spread of disease and for furtherance of its activity is through the family lines. They do not propose positive remedies for the eradication of the family cluster evil because it lies too much enmeshed with other social misfortunes to offer one opportunity to isolate and exterminate easily the trouble.

At the sanatorium, in the matter of preventive tactics, they come to the point of contact with the family cluster evil in this way: A far-advanced consumptive, incurable and hopelessly ill, beseeches his family to take him home. The family, overcome with sympathy and fraternal pity, is inclined to accede to the patient's wishes, even though there are only scant means with which to care for him properly at home, and what is most important, no safe place to house him in such a way as to preclude danger of contaminating the several young children of the family. If the family is patiently remonstrated with, and if they can be impressed with the full significance of the family cluster danger, some success may be met with in preventing a further extension of phthisis in their midst.

23. Diagnosis of Typhoid on Admission to Hospital.—Shattuck and Lawrence urge that typhoid should be suspected until some other diagnosis seems reasonably certain. Mean while, these patients should be treated under precautions to prevent the possible spread of infection. If this be done, it is possible to avoid risk of spreading infection in nearly all instances. In their series of 100 non-typhoid patients of fourteen years of age or older in which typhoid was suspected, bronchitis, broncho-pneumonia and influenza represent 29 per cent., or nearly one-third of the whole, undiagnosed fevers 15 per cent. and gastro-enteritis, diarrhea and colitis 12 per cent. Absence of rose-spots at the first examination has little weight for diagnosis. The same is true of splenic enlargement when not demonstrable by palpation, and of the Widal test when negative.

A positive Widal test is regarded as of the greatest importance. Typical rose-spots are very important and a palpable spleen is a valuable indication of typhoid, but is common in various conditions simulating typhoid. Atypical rose-spots are valueless for diagnosis. Absence of leukocytosis in a febrile disease strongly suggests typhoid. A white-count below 5,000 is a valuable indication of typhoid fever, and is unusual in conditions simulating typhoid. A white-count above 9,000 is presumptive evidence against typhoid. Bronchitis has no weight *per se* either for or against the diagnosis of typhoid fever. Ordinary bronchitis patients, as a rule, entered the hospital during the first week, and typhoid with signs of bronchitis generally during the second week of illness. Congestion of the bases of the lungs, when present in febrile disease uncomplicated by cardiac insufficiency, points to typhoid. The temperature in typhoid is seldom below 101 F., whereas in other conditions simulating typhoid the temperature is commonly below 101 F. In typhoid, the pulse-rate is more apt to be low in proportion to the temperature than in other diseases.

27. **Circulation in Man.**—In the cases of anemia studied (pernicious anemia, chlorosis and secondary anemia) the blood-flow in the hand is smaller than the normal flow. Accepting Plesch's result, that the minute volume of the heart is increased in the anemias, the diminution in the hand flow is interpreted as a sign of a vasoconstriction in peripheral parts, which facilitates the increased flow through the lungs. The deficiency in the hand flow is less in the chlorotic group than in the other cases of anemia. The explanation suggested is that the increased total volume of the blood in chlorosis permits the normal amount of hemoglobin to circulate through the lungs without a marked increase in the peripheral vasoconstriction. The view that the diminution in the cutaneous blood-flow in anemia is a necessary compensatory arrangement for increasing the flow through the lungs affords a natural explanation of the beneficial effect in many cutaneous disorders of general measures, especially those aimed at improving the quality of the blood. In a case of bradycardia with a pulse rate permanently below 40 during rest in a sitting position, the hand flow was normal.

28. **Intestinal Obstruction.**—Hartwell claims that the length of life is in inverse ratio to the damage occurring in the intestine. All the animals in his experiments were under practically identical conditions as far as the stagnation of the intestinal contents is concerned, and if the poison arose from this source, or from functional changes in the mucosa, he claims they should have lived approximately the same time. A simple explanation is offered for the varying damage to the intestine. When antiperistalsis is sufficient to empty the intestine toward the stomach, no damage results. When this is absent the accumulated secretions distend the bowel until the circulation is obstructed and the damage results. The administration of saline subcutaneously exerts no influence either on the production of the poison under this condition, its absorption, or its elimination, and the dogs sicken and die in spite of this treatment. He cites examples to show that in the absence of damage to the intestine no symptoms of poisoning arise, provided the water lost by vomiting is replaced, and in the presence of such damage no amount of saline will, to an appreciable extent, affect the development of poisoning, or prevent death.

To Hartwell the conclusion seems inevitable that the only poison present in intestinal obstruction arises from the damage secondary to the obstruction, and not from the stagnation of intestinal contents or an altered function of a normally appearing mucosa. As final proof of his position, he reports that by exercising great care in avoiding damage to the intestinal wall, it is possible to keep dogs with the closed loop alive for comparatively long periods. He sounds a note of warning, viz., that the application of these facts to intestinal obstruction in man must be made with reserve. The human intestine is apparently incapable of withstanding the same amount of distention without damage, and consequently a poisoned condition occurs earlier in man. However, there are two important results of this experimental work. The need of large amounts of saline subcutaneously is proved, and has been used by Hartwell with advantage, patients having readily absorbed three to six quarts in twenty-four hours. He says there is no necessity of draining out the intestinal contents unless the bowel is damaged. Simple stagnation does not yield a poisonous substance, and consequently the release of the obstruction by operation is sufficient. When, however, strangulation has begun, the material above the obstruction should be removed, and if extensive damage exists a continued drainage through an enterostomy may be needed.

30. **Visceral Organisms.**—Since June, 1912, Carrel has been working to develop a technic by means of which a system of organs could be made to live and functionate when separated from the other organs. The present method consists in removing aseptically the abdominal and thoracic organs of an animal and in preserving the organs in an incubator at a temperature of 38 C., while the lungs are being artificially ventilated. The thorax and abdominal viscera, united by their blood-vessels, were removed from the cadaver of the animal and placed in a tray containing Ringer's solution at a temperature of about 38 C., in such a manner that the lungs floated on the surface of the fluid and the heart was suspended underneath in the liquid. When this position was reversed and the heart was placed above the lungs the circulation was somewhat impaired. The temperature of the Ringer's solution was maintained constant by means of an electric pad placed under the tray, or simply by the addition from time to time of Ringer solution at the right temperature. Ordinarily the heart still pulsated slowly and regularly, but the blood-pressure was low and the appearance of the organs anemic.

After a few minutes the blood-pressure began to rise, and in a few cases became almost normal. Generally it remained low and sometimes the heart entirely ceased beating. Then a transfusion was made from the carotid artery of the first animal to the inferior vena cava or abdominal aorta of the visceral organism. When the pressure was very low or when the pulsations of the heart had completely stopped, the transfusion was made directly through the aorta, in order to reestablish immediately a normal circulation through the coronary arteries. The heart started almost immediately to pulsate normally. As the condition of the heart improved the transfusion was made through the inferior vena cava. It was possible in that way to inject quickly a large quantity of blood into the visceral organism. Immediately after the transfusion the lungs became pink, the heart beat strongly from 120 to 150 times a minute, and the blood-pressure often rose above normal. The abdominal aorta pulsated violently and strong pulsations could be seen in the arteries of the stomach, liver, kidney, intestine and even of the ovaries. Peristaltic contractions of the stomach and of the intestines were observed. The spleen, which was bluish, assumed its normal appearance. After a few minutes all the viscera were apparently normal.

Then a careful hemostasis of the posterior branches of the thoracic aorta was made and all the forceps were removed. It was important to ascertain that no hemorrhage, even one from a very small vessel, was taking place. If a few minutes after the transfusion the pressure was still above normal, a certain quantity of blood was allowed to flow from the lower part of the abdominal aorta. Then the appearance of the viscera exactly resembled that of a normal animal. The visceral organism was placed in a tin box filled with Ringer solution, and covered with Japanese silk and protected by a glass cover. The tracheal and esophageal tubes were fastened to proper openings in the anterior part of the box. The intestine was pulled through a glass and rubber tube fixed in the posterior wall of the box. The end of the intestine was fixed by circular suture to the edge of the rubber tube, an artificial anus being made. The box was put into an incubator at a constant temperature of about 38 C. Artificial respiration was carried on by a current of air interrupted about twelve times a minute. The compressed air was furnished by means of an automatic electric apparatus pumping air into a tank, from which it was given to the animal under the proper pressure. Water or food could be injected into the stomach through the esophageal tube. The urine could be collected from the bladder through a tube, but it was generally aspirated from the bladder with a needle, when samples of urine were taken for study. The feces and intestinal secretions were received outside of the box from the artificial anus.

It was then observed that during the hours following the operation the viscera had the same appearance as those of a living animal. The contractions of the heart and the circulation of the organs were apparently normal. Pulsations could be seen in the smaller branches of the mesenteric artery. The intestine emptied itself through the artificial anus by means of regular peristaltic contractions. When the intestine was empty, bile and intestinal juices were evacuated. In an experiment in which the stomach was full of meat at the time of death, digestion took place. At least 90 per cent. of the amino-acids injected into the intestine were rapidly absorbed. There was also an abundant secretion of urine, which was collected into the bladder. After five or six hours hyperemia of the peritoneum of the intestine appeared. It seemed as though a peritonitis developed progressively, and in some cases the intestines became paralyzed after eight or nine hours, although their circulation was still very active. Abundant hemorrhage could still be produced by section of a small branch of the mesenteric artery.

Some of the visceral organisms died almost suddenly after three or four hours, but most of them were in a normal condition ten and even twelve hours after the death of the animal to which the organs belonged. The death of the organism was announced by some irregularities in the pulsation of the heart, which was also weaker. Then the heart stopped suddenly. In one experiment the death of the visceral organism occurred thirteen and one quarter hours after the death of the cat from which it was taken.

34. **Rate of Absorption of Epinephrin.**—Kleiner and Meltzer found that subcutaneous injections of epinephrin are, in contrast with its behavior in the production of the other effects of that drug, more favorable to the production of glycosuria in rabbits than intramuscular injections: the failures are fewer and the quantities of dextrose in the urine are generally larger. In general, as regards the stimulation of diuresis by epinephrin, a subcutaneous injection exerts generally a greater effect than an intramuscular one. Subcutaneous injections of a certain dose of epinephrin distributed over several areas are far less effective than the administration of that dose in a single injection; they fail frequently to produce any glycosuria, the quantity of dextrose in the urine, when present, being less, and the quantity of urine being generally diminished. Apparently, the more slowly the injected epinephrin reaches the blood, the greater is its effect in producing glycosuria and generally, also, the greater its diuretic action.

64. **Treatment of Pneumonia.**—To an isotonic saline solution given intravenously Berlin has added iodin solution, to which were also added creosote and guaiacol for their anesthetic and germicidal action. The creosote acts strongly as a sedative to pain, relieves congestion, and greatly relieves dyspnea, making the patient more comfortable immediately. Although the number of patients so treated during the past two years has been too small to be conclusive, he says, that every patient has recovered in spite of the fact that several had been given an absolutely bad prognosis by competent consultants.

83. **Dysentery in the Tropics.**—Amebic dysentery, according to Whitmore, is endemic and does not ordinarily give rise to epidemics: bacillary dysentery gives rise to extensive epidemics. Amebic dysentery is due to a protozoon; bacillary dysentery is due to a bacillus. In amebic dysentery the process begins in the submucosa, from the specific tissue destroying property of the amebae which have traveled in through the mucosa; bacillary dysentery is a diphtheritic or croupous process, involving the intestinal mucosa, and the submucosa is only secondarily involved. Liver abscess is a frequent complication in amebic dysentery; it is very rare in bacillary dysentery. Amebic dysentery tends to become chronic, with amebic relapses: bacillary dysentery is a self-limited disease, with a tendency to complete recovery. Ipecac, in the form of emetine, is specific in amebic dysentery; a specific antitoxic and bactericidal serum gives the best results in the treatment of bacillary dysentery.

88. **Use of a Very Minute Dose of Tuberculin.**—With the exception of the method of White and Van Norman, Cohen says, there is no way of ascertaining beforehand the proper therapeutic dose of tuberculin for the individual patient, or the amount that will produce a reaction in that patient. Only by beginning tuberculin treatment with a dose smaller, or at least no larger, than the one that will benefit the patient, or produce a reaction, can one obtain the good effects and avoid the harmful action of this dangerous agent. In giving tuberculin, aim to begin with less than the amount required. In other words, give a safe dose. An initial dose larger than 0.000001 milligramme will probably produce a reaction of greater or less severity in the majority of tuberculous subjects. It can be given, therefore, only to a limited number of selected patients. The number of tuberculous patients who will exhibit a severe reaction to 0.0000001 milligramme of tuberculin is probably small. Hence, this is a safe dose for the average sufferer from tuberculosis, with the exception of advanced, toxic patients. As tuberculosis is usually a chronic disease, and its treatment prolonged, there can be no serious objection to taking a little time to determine the proper dose of tuberculin for the individual patient, especially if by so doing we avoid harming him. There is no immediate hurry. The proper method of giving tuberculin, therefore, would be to begin with 0.0000001 milligramme, or 0.00000001 milligramme, and if this dose should be found to be too small, to gradually increase it until the proper dose is reached. With this method Cohen states, tuberculin therapy will be robbed of its greatest danger, and many more patients will be able to take tuberculin than are now considered suitable for the excessive doses in general use at the present day.

99. **Use of Phosphorus in Diseases of the Lungs.**—Phosphorus in doses of 1/1000 of a grain has been successfully administered by Lemon in all classes of cases of lung disease during the past eleven years, and though, in the majority of cases it has been used in combination with other drugs, occasionally necessity compelled the use of it alone, and the success which has attended all cases where it has been used Lemon ascribes largely, if not altogether, to its presence in the mixture.

16. **Auricular Fibrillation.**—The authors point out that while the exact cause of auricular fibrillation is unknown, it usually comes on in a heart in which there has been for a considerable period disease of the valves or myocardial change from inflammation or degeneration. Sometimes it arises suddenly where there has been no previous sign or symptom of heart disease. The authors suggest that possibly in some of these cases it occurs in hearts which were previously perfectly healthy. If this is true its essential cause must lie outside the heart and not in any anatomic or pathologic change in the heart itself. Sudden death in auricular fibrillation is probably due to the onset of fibrillation of the ventricles, and that some cases of sudden death both in diseased and healthy persons may be due to the simultaneous onset of fibrillation of both auricles and ventricles.

18. **Pulsus Alternans in Myocardial and Arterial Disease.**—Windle has had forty-five patients under observation, showing the pulsus alternans in the following conditions, stated in order of frequency: 1. Arterial and myocardial disease. 2. Chronic heart disease due to rheumatism. 3. Pneumonia. 4. Paroxysmal tachycardia. 5. Acute rheumatic carditis. It is Windle's experience that the presence of the pulsus alternans in a case of myocardial and arterial disease always adds to the gravity of the prognosis. It signifies disease of the heart progressing inevitably to a fatal end; and this is its meaning when present, as it not seldom is for a time, in patients whose clinical condition does not suggest serious unsoundness of the heart. In the case of thirty-three patients with myocardial and arterial disease under his observation, the diagnosis of the pulsus alternans was established in each case by polygraph tracings; and records were taken systematically during the time the patients were under notice. Five of these patients died within a year; two lived eighteen months, and two twenty-four months after the pulsus alternans first showed itself. Windle says that when once the pulsus alternans appears in a patient the subject of arterial disease it will never again be absent for long. The reason for its permanence in these cases is that the exhaustion of the heart which it expresses is due to degeneration of the heart muscle. In the early stages alternation becomes latent for a time through bodily rest, or the action of drugs which slow the heart, but eventually persists with rest and in spite of any measures of treatment yet tried.

20. **Pneumothorax Treatment of Tuberculosis.**—The authors report eleven cases of pulmonary tuberculosis in which they produced an artificial pneumothorax by means of nitrogen. Their results in summary are as follows: Case 1. Mainly monolateral tuberculosis of the lungs. Prognosis unfavorable. In consequence of the artificial pneumothorax a further development of the disease was averted and the toxic influence of the large infiltration of the right middle and lower lobe was eliminated, as shown by the disappearance of the fever. A complete cure was impossible on account of the large cavity, but this had become smaller by a half during the year of the duration of the pneumothorax. It was, however, impossible to eliminate the influence of the intoxication of the whole organism, after some years of illness, and entirely to check the secretion of the cavity. The fatal issue was entirely due to the amyloid degeneration of the kidneys, which had been diseased for sixteen years. The condition of the compressed lung, as shown at the autopsy, was absolutely satisfactory, from the point of view of the success of an artificial pneumothorax. Case 2. Monolateral tuberculosis of the whole left lung, with tendency to hemoptysis, which indicated the necessity of an artificial pneumothorax. In this case the hemoptysis was entirely checked. There was a general amelioration and capacity to resume work. Seven months afterward, when all the nitrogen was absorbed, a relapse (entirely due to his own carelessness) occurred, rendering the prognosis extremely doubtful. In future, the authors state that they will, with similar cases, go on with the punctures for a long time, if only to keep such a patient under medical control. The success in this particular instance can be claimed as definite, and the hemoptysis was completely checked.

Case 3. Advanced monolateral phthisis with large apical cavity. The operation produced a compression, and the expectoration was greatly and definitely reduced. Contrary to their expectations, it was impossible to produce a partial pneumothorax in a case which *a priori* did not seem to be a favorable one for this form of treatment. Case 4. In this case of advanced monolateral tuberculosis, evidencing activity and deterioration, the operation of pneumothorax produced a wonderful effect. In a short time all symptoms of deterioration and toxity were completely arrested. Case 5. Advanced monolateral tuberculosis of the right lung, with pyrexia. After operation, disappearance of fever, decrease of cough and expectoration. A durable result is probable, although the patient is not sufficiently careful, thereby undergoing considerable risk. Case 6. Advanced tuberculosis of the entire left lung with a hopeless prognosis: high hectic fever for three years, abundant expectoration; a picture of general deterioration and daily loss of ground. But, after the compression of the lung, there was instant cessation of the fever, with decrease of sputum to one-fifth of its quantity. Five months only have lapsed since the production of the pneumothorax, and a very considerable time must pass before a definite healing takes place, but the authors are justified in hoping that this healing will be effected, if the organism, which for so long a time was weakened and intoxicated, has sufficient power of resistance to conquer the alteration of the circulation. In any case, this patient's life has been for the moment saved by the production of an artificial pneumothorax.

The remaining five cases were not so definitely successful. Personal experience with the pneumothorax treatment convinces the authors that many apparently hopeless cases of monolateral tuberculosis of the lungs can be arrested, and, further, may be healed, and even if perfectly satisfactory results are few and far between, the trial of the treatment is legitimate.

22. **Salicylate in Acute Rheumatism.**—The objection that the larger doses of salicylate do not imply increased absorption of the drug is held by Miller to be without foundation. The objection that the larger doses are too prone to produce vomiting to be of value, he says, is only partially true. The production of vomiting is more a matter of the type of case under treatment and the methods of administration than the size of the dose employed. The vomiting produced in severe cardiac cases must necessarily be a limitation to any antirheumatic action which the drug may possess in rheumatic carditis. The objection that large doses are too prone to produce acid intoxication to be of value is also only partially true. The method of administration is of more importance than the size of the dose. The objection that the larger doses are dangerous and tend to increase fatalities, Miller states,

is not supported by the series of cases examined. It is again a question of knowing how and when to use the drug. The objection that the specific use of salicylate is unsound, as relapses, particularly of nodules, are not prevented, is not well supported by the series of cases examined. Most of the relapses occurred on or after small doses or a short period of administration of the drug: cases taking large doses showing some immunity to relapses. Nodules are not generally more commonly found in relapses than are other manifestations; and where they develop under large doses it seems that they signify little, if any, fresh activity on the part of the infection.

23 *Diffuse Edema of the Fetus. C. Sauvage.
24 Dissecting Mole. Curtis and Oui. Commenced in No. 6. See Abstract 63, p. 439.

23. **Diffuse Edema of the Fetus.**—Sauvage has recently encountered two cases and discusses the factors engaged in the production of the fetal edema. In some cases malformation of viscera or abnormal composition of the blood is evidently responsible, both a mechanical cause and a toxic cause being possible. When the placenta is likewise edematous, a toxic origin is more probable, although the edema may back up into the placenta; Fischer has recently reported a case in which the edema in the fetus was undoubtedly due to mechanical causes but the cord was very short and the placenta was also edematous, weighing 500 gm. In one of the personal cases reported Sauvage found that the proportion of sodium chlorid in the blood was much above normal and it was still higher in the edema fluid than in the blood-serum. These facts are significant as they suggest that an excess of sodium chlorid or retention of sodium chlorid in the mother may have been responsible for the diffuse edema in the fetus. The excessive proportion of sodium chlorid in the fetal fluids was accompanied by serious lesions in the liver, kidneys and spleen. The mother's kidneys were not functioning properly, the insufficiency of the kidneys being manifested by edema during the pregnancy and by tests repeated three weeks after delivery. She was a woman of 44 with no morbid antecedents except edema and lassitude during her three previous pregnancies, two of them terminating by the death of the fetus. There is evidently chronic nephritis but it persists latent except when the kidney functioning is hampered by a pregnancy. There were no signs of syphilis in either case. Prouvost three years ago warned of the expediency of reducing the intake of salt during pregnancy.

29 Outward Dislocation of the Clavicle. F. M. Cadenat.

28. **Spontaneous Perirenal Hematoma.**—Lippens summarizes twenty-three cases from the literature and remarks that the symptoms closely resemble those of a ruptured tubal pregnancy. It has never been accurately diagnosed before the operation; left to itself it is always fatal. The seven patients not given operative treatment all died. Even at the best, the outlook is serious as 25 per cent. of the patients operated on succumbed. In ten cases the hematoma was merely opened and the pocket tamponed; four of these patients died. In six cases the kidney had been injured so much by the compression that it was at once removed, with recovery of five of the six patients. If the blood pours out copiously and persistently or if the kidney has been irreparably damaged, nephrectomy is indispensable. As the diagnosis is generally so uncertain, Lippens advises a transverse incision or Verhoogen's paraperitoneal incision.

31 *Treatment of Epilepsy. Pitres.

31. **Treatment of Epilepsy.**—Pitres remarks that the consensus of opinion is now that the seizures of epilepsy are brought on by some perversion in the metabolism of proteins, and consequently the diet should be regulated with this in view, keeping the unstable gastro-intestinal tract under constant supervision. De Fleury even forbids the use of milk and keeps his patients on a strictly vegetable diet, with as little salt as possible. Pitres adds that ligation of the carotids has two successful cases to its credit, and two out of six cases have been reported as successes following ligation of the superior longitudinal sinus. Operations on the sympathetic nerve and lumbar puncture have invariably failed to relieve, as also decompressive cranial operations in essential epilepsy. Regarding the seizures as due to a toxemia, elimination of the toxins should be promoted in every way, especially by venesection, withdrawing from 300 to 500 gm. of blood, following with infusion of 250 or 500 c.c. of saline, and flushing the intestines copiously with cold boiled water, giving the patient bromid in milk or in the saline infusion. Here lumbar puncture may render valuable symptomatic services, with cold baths if the temperature runs up. Symptomatic epilepsy subsides after removal of the cause, possibly by correction of a visual defect or removal of adenoids. Treatment as for syphilis may prove unexpectedly successful. Traction, compression or a ring of blisters above the part involved in jacksonian epilepsy may also cure the tendency to spasm. He has witnessed a complete cure follow the application of ten or fifteen blisters in turn one above the other.

35. **Radioscopy of the Stomach.**—Martinet and Meunier state that the bismuth gruel which the patients are given for radioscopy is a most unappetizing mess, generally choked down by the patient with repugnance, and it does not elicit

the normal responses in the stomach. Consequently the findings on radioscopy are not those of the physiologic functioning of the stomach but represent conditions quite different from those that follow an ordinary meal eaten with appetite. Consequently they declare that the findings are no criterion of the actual functional condition of the stomach. They suggest that the patient should take an ordinary test meal, made appetizing, and the bismuth suspension should be taken after a given interval: this would surprise the stomach at its normal work and the findings then would be truly instructive.

36. **Biochemical Aspect of Alcohol Intoxication.**—Nicloux describes a method with which he has been able to detect minute amounts of alcohol in the blood and other fluids and tissues of the body and of the fetus, and reports his findings therewith. He distils out the alcohol after mixing the substance to be examined with picric acid, and estimates the proportion present by the bichromate-sulphuric acid method. Among the practical results of his research are the constant findings that alcohol ingested passes directly into the genital glands and secretions in considerable proportions. The alcohol seems to pass with exceptional facility into the testicles and into the fetal blood. When the male organism is under the influence of alcohol it passes into the testicles, prostate and the semen, the toxic action of the alcohol thus being liable to be directly exerted on the ovum when fecundation occurs under the influence of alcohol. On the other hand, alcohol taken by a pregnant woman at any time during her pregnancy is liable to pass directly into the blood of the fetus, the tests showing very little difference between the alcohol content of the maternal and the fetal blood. Outside of pregnancy, the alcohol passes to the ovary and into its secretion. Alcohol passes rapidly out of the system, in twenty-four hours at most. But during this period, if fecundation occurs, it is while the genital glands and genital secretions are feeling the noxious influence of the alcohol poisoning the spring of life at its source.

43. **Pathogenesis of Epilepsy.**—Pierret found by animal experimentation that epilepsy can be produced by various sorts of traumatism of the nervous system. He believes that in many, perhaps all, cases of so-called idiopathic epilepsy the patients have had some infectious disease localized in the nervous system, leaving behind it cicatricial areas. Later some intoxication takes place and toxic products, acting on these sclerotic foci, cause convulsions, which may be motor, sensory or psychic. The rational treatment therefore is to protect the patient from all possible causes of intoxication from within or without.

47. **The Epidural Space.**—Heile describes the technic with which it is possible to inject an anesthetic or other fluid into one side of the epidural space and thus act directly and exclusively on the nerves on that side. The best results with this as with all other methods of treatment of sciatica are obtained in the cases in which there is no inherited taint of the kind, the patients had been previously healthy and the nerve shows signs of irritation, namely, tenderness along the nerve, hyperesthesia of the skin, especially in the area of the fifth lumbar vertebra, Lasègue's sign, etc. With a history of preceding rheumatism or sciatica in the parents, the epidural injections may temporarily relieve but there are generally more or less irreparable lesions and a tendency to atrophy of the gluteal muscles and the muscles of the legs, and more or less changes in the reflexes. When he notes these signs of neuritis of the roots, he abandons hope of a permanent cure from the epidural injections. If the patient insists he injects merely 30 or 40 c.c. of a hypotonic salt solution to refrain from further irritating the nerve. The injection may even aggravate the pain in these cases; much better results are liable to be attained with weak galvanic electricity. On the other hand, in the first group of cases, especially when complicated by scoliosis of the lumbar vertebrae, suggested early by the lowness of the anal fold on the affected side, most excellent results followed the injection after the failure of months of other measures, internal and external. In these cases he injected as large amounts of the fluid as possible, from 80 to 150 c.c., injected through the sacral foramen or into the spine, aiming to loosen up the nerve itself, cause it to swell and thus promote the softening up and absorption of the products of inflammation. This swelling up of the nerve is a painful process, and this pain is the sign that the nerve itself has been reached. It may require ten such injections to complete the cure, and it is difficult to convince the patients of the advantages of submitting to repetitions of this painful procedure. Consequently the sphere of the method is limited. He has never witnessed any durable untoward by-effects from it in any instance. The epidural space cannot be depended on for reliably blocking the nerves for local anesthesia. The article is illustrated.

52. **Spontaneous Healing of Wounds in the Lungs.**—Tiegel reports the case of a man of 38 who had five ribs fractured by a falling beam and the lung ruptured. Emphysema developed over nearly the whole trunk and head. As the suffocation became threatening, Tiegel made an incision 4 cm. long in the neck, down to the trachea, and applied a vacuum cup connected with a water jet pump, with valve regulator. The negative pressure in the cup was kept at 30 cm. water. The result was immediate relief and in half an hour the patient was able to open his eyes, which before had been impossible from the emphysema of the lids. The aspiration stopped at one time but continued after the pressure had been temporarily increased, aspirating fluid along with the air. Recovery was prompt and smooth, the lung healing spontaneously in five days as was evident from the behavior of the interposed

valve. Tiegel thinks that the results in this case were better than could have been attained with any operation, no matter how extensive. He gives further illustrations of the lungs from six dogs showing the smooth spontaneous healing after extensive stab wounds. One lung showed the wound tightly stuck together forty hours after the injury, sustaining pressure up to 45 mm. mercury. These experiments not only illustrate the remarkable tendency to spontaneous repair and healing but also the spontaneous arrest of hemorrhage after such injuries of the lungs.

56. **Disappointing Outcome of Bone-Peg Arthrodesis.**—Schewandin was able to reexamine recently five patients who had been treated by Lexer's technic for paralysis of the ankle, driving a peg of bone into the joint. The peg was taken from the tibia or the fibula of the leg above, with its marrow and periosteum. Besides the five cases described in detail he has records of four other patients, all with an interval of from two to five years since the operation. Good results were obtained in only a very few instances; the bone was gradually absorbed and then conditions were no better than before the measure had been applied. None of the patients experienced any ill effects from the operation on the bone above, and only one of the patients had pain in the pegged ankle, but as the bone peg was absorbed, the joint grew loose again and the toes or the whole foot dragged.

61. **Operations on the Seminal Vesicles.**—In two of Voelcker's fourteen cases the operation on the seminal vesicles was done for a tuberculous process, once for myoma, once for carcinoma, this patient dying six months later from metastasis. In three other cases the trouble was an infectious catarrh of the bladder and kidney pelvis involving the seminal vesicles; in another case the inflammation in and around the seminal vesicles was the work of the gonococcus and the kidney pelvis was also involved. Marked improvement followed the operation although this patient is still under treatment for his pyelitis; the anticipated abscess in the vesicle region was not found and the trouble must have been merely acute inflammatory adhesions. A simple incision seemed to answer the purpose and the relief was so prompt and complete that Voelcker commends this little operation in such cases to ward off danger from obstruction to the outflow of urine from the kidney pelvis. Only he advises in this case to keep the wound open to drain for several weeks; the two weeks of drainage in his case were evidently not long enough. There was slight fever after the drain was removed and pain in the kidney, but these disturbances were transient. In another case a focus of inflammation had persisted in the seminal vesicles and was evidently the source for recurring gonorrheal joint trouble; the operation on the vesicles was followed by permanent subsidence of the joint symptoms. The second day after the operation the patient said that his previous pain in hip, shoulder and heel was gone; by the fourth day he had no pain except in the costal arch, and by the end of the second week he was free from pain of all kinds but the joints were still stiff. In another case pneumococci were responsible for the vesiculitis; there was no history of gonorrhea. This patient was a man of 59 who for two years had had pains on micturition and there was about 45 c.c. of residual urine. During the last year there had been pains in the sacral region and increasing stiffness in the lumbar spine, knees and hip joints so the patient could walk only with difficulty. The prostate was of normal size and soft but the vesicles were 7 and 8 cm. long and much swollen. The joint troubles have been much improved since the operation, and it is possible that the swelling of the seminal vesicles may have induced them by reflex action as there was nothing else found to explain them; the nervous and cardiovascular systems seemed to be clinically normal. In these and the other cases the assumption that the chronic inflammation of the seminal vesicles was responsible for the pains and stiffness in the joints is rendered plausible by the relief that followed the operation on the vesicles, although Voelcker never witnessed such wonderful results as Fuller has reported. The causal relationship with bladder and kidney affections seems more obvious

62. **Shutting Off the Blood from the Brain for Operations.**—Ritter reports three cases and numerous experiments on animals which apparently sustain his assertion that both carotid arteries can be clamped for a period of thirty minutes, thus shutting off the blood supply to permit an extensive operation on the skull, without permanent injury to the patient. His experience further shows that anemia of the brain for a period up to thirty minutes, from criminal violence or trauma, does not necessarily entail irreparable lesions and permanent cerebral disturbances.

64. **Comparative Pathology in Plants and Animals.**—Baur gives an interesting review of the analogies and the differences between pathologic processes in the vegetable and animal kingdom. The fungi are the most prominent parasites of plants but there are a number of true bacterial affections in plants. Their effect seems to be exclusively local, no general influence ever being apparent from them, and hence there is no production of antibodies in plants. New growths on plants may resemble tumors on animals, but their etiology is even more obscure and there seems little hope of their helping to clear up the problem of cancer.

65. **Action of Calcium on the Kidneys.**—Jacoby reported last year the history of a case of fibrous ostitis in which a brilliant cure followed administration of calcium and the metabolic findings showed retention of calcium at the time and later. When treatment was commenced there was an exaggerated output of calcium in the urine, even more than ever occurs with phosphaturia, but under treatment with the calcium salts the output declined. In order to explain this apparently paradoxic phenomenon, Jacoby gave calcium to dogs after glycosuria had been induced by the subcutaneous injection of phloridzin. At once or more gradually the urine contained less and less of sugar, acetone and nitrogen until finally it became nothing but almost clear water; the elimination of water did not seem to be affected. When there was no further elimination of anything but water, the dog died. The calcium salts used were the chlorid, acetate and lactate. An unmistakable function-reducing influence from them was apparent, and Eisner confirms this by report of similar experiments on five patients with kidney disease and two healthy persons with thirty examinations made of the output of sugar, acetone, albumin and nitrogen before administration of the calcium salts and thirty again afterward. In a few cases the kidney functioning showed no difference; it persisted equally good or equally bad after the calcium had been taken, but in the other cases a marked function-reducing action was unmistakable. The findings after death in the dogs and the clinical experiences seem to show that the kidney filter becomes less porous—possibly from mechanical obstruction by the calcium particles. Eisner declares that a drug which can thus cause retention of substances, natural or

foreign to the organism, must be used with great caution as the effect is a direct impairment of kidney functioning. The fact that the percentage of albumin becomes reduced under the influence of the calcium is liable to be misinterpreted as a sign of improved kidney functioning, when in reality it is just the reverse.

66. **Influence of Salvarsan on the Kidneys.**—The research reported confirms the injurious action of salvarsan on kidneys which are already suffering from the action of mercury. Experiments on dogs under the influence of mercurial intoxication showed that the injurious influence was most marked on the water-eliminating function, up to complete anuria. It was found further that the urine might persist free from albumin to the end. In some of the dogs complete anuria followed the injection of salvarsan. In giving salvarsan, therefore, the necessity for supervising the diuresis is at once apparent, and the unreliability of trusting to the albumin content as an index of the functional capacity of the kidneys. The research reported further emphasizes that the danger from salvarsan is materially enhanced when the kidneys were not previously sound or were suffering from the effects of systematic mercurial treatment. It warns further against the practice of a combined mercury-salvarsan course of treatment.

69. **Adiposis Dolorosa.**—Kloninger's patient was a woman of 51 with a typical case of the painful deposits of flesh to which Dercum has given the above name. Besides the pain, restlessness and "hot flashes," there was much physical depression. An ovarian tumor had been removed two years before and the symptoms had come on since then. She was given thyroid tablet treatment systematically for four months, after which there was marked subjective and objective improvement. Mild hydrotherapy aided to complete the cure, with massage after the tissues had become less sensitive. From a helpless, bed-ridden condition, the woman is now able to be up and about, free from pain, "flashes," etc. Sézary recently published a similar case in which a course of ovarian treatment failed to relieve but a change then to thyroid treatment was speedily followed by a complete cure. Fresh thyroid was given in this case.

70. **Abortion.**—Hammerschlag insists that unless there are unmistakable signs of actual abortion, such as expulsion of scraps of fetal membranes, rudimentary contractions of the uterus, possibly only to be palpated and not experienced by the patient as pains, gaping of the internal os, fever, etc., uterine hemorrhage during the first months of a pregnancy should always be treated on the principle of preserving the pregnancy. The statements of the patient must generally be disregarded. Fromme found that 17.9 per cent. of 157 women with more or less uterine hemorrhage during the first months of pregnancy went on to term, and all but three had well developed children. Three had had hemorrhage for five days, three for a week, five for two weeks, three for three weeks, three for four weeks, seven for from five to seven weeks, one for three months, and one uninterruptedly for five months. Besides these groups, three other women went on to term after having had hemorrhage during the later months of the pregnancy. Hammerschlag says that with missed abortion, treatment should be expectant unless forced by complications. Febrile abortion, with the infection restricted to the uterus, requires its evacuation but done with extremest care to avoid injury to the tissues. Do not dilate the cervix unless absolutely necessary and then do it with laminaria, not metal. Then rinse out the uterus with 50 per cent. alcohol, then separate the membranes with the finger, not the curet. Then remove the scraps with the abortion forceps introduced under the guidance of the eye or with two fingers inserted in the cervix. The forceps must never be introduced farther than to just above the internal os. The scraps are worked into its jaws with the fingers, and the forceps is then drawn out and the uterus cavity examined with the fingers anew for more scraps. It is remarkable, he states, how even the inexperienced can thus clear out the uterus without injury to the tissues when a forceps without any sharp edges (Winter's) is used in this cautious manner, always under the guidance of the fingers.

71. **Air in the Abdomen after a Laparotomy.**—Cohn says that in a number of instances he has found that the supposed tympany following operation was merely the result of the presence of air sucked into the abdomen during the laparotomy. In most cases the air is gradually absorbed without harm, but if the heart is frail, the upward displacement of the diaphragm from the air, which naturally rises to the top of the abdominal cavity, may hamper it seriously, besides the effect on the respiration and intestines. The air may even compress the intestines enough to aid in producing postoperative paresis of the bowels. In one case during injection of nitrogen to make an artificial hydrothorax some of the gas escaped into the abdominal cavity and it was not completely absorbed until after six weeks.

89 Electric Treatment of Obesity. (Erfahrungen mit dem Bergonisieren, einer neuen Methode für Entfettungskuren und Muskelgymnastik.) A. Veith.

79. **Azoospermia after Epididymitis.**—Fürbringer concludes from his own and others' experiences that bilateral tuberculous epididymitis is less liable to entail azoospermia than the gonorrheal. His experience in more than a thousand cases of azoospermia has been that it is incurable in about 80 per cent. of the bilateral gonorrheal cases; others have reported still higher percentages. On the other hand, the anatomic conditions with a tuberculous process may leave the passage partly permeable.

80. **Exudates in Aleukocytic Animals.** — Lippmann and Plesch found that absolutely no leukocytes could be detected in the blood of guinea-pigs after intracardial injection of thorium x. The local response then to injection into the peritoneum of a culture of swine-plague bacilli was a local exudation exclusively of monocytes. Irritation of the muscle induced merely necrosis, no inflammation. The small lymphocytes must consequently be derived from the endothelium and have no specific antigen character.

81. **The Blood after Thyroidectomy.**—The research was done on dogs and the minute details of the blood before and after are tabulated. The animals developed a secondary anemia usually about a week after the removal of the thyroid and

the blood-count revealed injury of the bone-marrow functioning, as in anemia from the action of blood-poisons. There was usually a relative lymphocytosis, the experimental results thus harmonizing with clinical experience.

82. **Diagnosis from the Blood in Psychiatry.**—Schultz supplies data to show that the leukocyte count has great differential value in psychiatry, especially in the diagnosis of epilepsy and dementia praecox. The stupor in the latter seems to be accompanied by a specific blood-picture, *especially an accumulation of erythrocytes in the capillaries of the lobe* of the ear. This "capillary erythrostasis" is the hematologic manifestation of the "pseudo-edema" of dementia praecox.

83. **Acidity of the Stomach with Gall-Bladder Disease.**—Ohly states from his research on forty-three patients with gall-bladder disease that with incipient trouble of this kind the gastric acidity seems to be above normal. As the gall-*bladder disease* progresses, however, the gastric acidity declines until there is anacidity or actual achylia in about 70 or 80 per cent. of all cases *of cholecystitis. This* subnormal acidity should be borne in mind in treating the cholecystitis, and it also may aid in differentiating between pyloric or duodenal ulcer and cholelithiasis in some cases.

85. **Intracranial Access to the Hypophysis.**—In a case described the tumor in the hypophysis had grown inward and was thus accessible only from directly above. Rupp found it feasible and comparatively simple to *turn back a bone and* soft part flap from *the orbit to the coronal suture, push* the brain out of the way and shell out the tumor. There proved to be already metastases in the brain and elsewhere so the operation failed to cure the patient. He survived thirty hours and there was no trace of postoperative paralysis, but he did not regain consciousness although still responding to external stimuli, and micturition was spontaneous.

86. **Cultivation of Syphilis Spirochetes.**—Schereschewsky calls attention to the extremely simple and reliable technic which permits cultivation of the spirochetes in pure cultures. The medium is sterile serum derived from different horses. A test-tube is filled nearly up to the cork with this serum and heated in a water bath at 65 C. until it is no longer fluid. An aseptically excised syphilis papule is then pushed half way down into the test-tube, with care not to disturb the serum any more than is actually necessary. Tapping on the side of the tube will let any air left in the tube escape. The tube is then plugged tight with the cork *again and* kept at 37 C. for eight days. The tube is then cut off below the papule and some of the culture medium is transferred to a slide and examined with the dark field microscope. The cork prevents the contents from drying out as with a cotton plug.

110 Diverticulum Above *Cicatricial* Stenosis *of the* Esophagus. *H.* Flesch.

99. **Dietetic and Therapeutic Treatment of Spasmophilia.**—Spasmophilia has been recognized as a clinical *entity only* for the past few years, since the method of *testing the muscles* for hyperexcitability *to the electric current has been in use.* Zybell reports twenty-nine cases in which *various dietetic* and therapeutic measures were tried. Two-thirds of the children were in their first year and half of them under 6 months of age. No special diet was found to have a uniform *effect on the* condition. The usual *practice* of keeping the *child* on starvation diet for twenty-four to forty-eight hours *he found* did more harm than *good.* He believes that spasmophilia is not due to a deficiency of calcium salts. Treatment with salts of calcium, *magnesium and* sodium had no effect. The only remedy that was found to have a uniform and pronounced beneficial effect was a solution of phosphorus in cod liver oil. Rosenstern recommends that in severe cases this be given in large doses—5 gm. five times per day of a solution of 0.01 gm. *phosphorus in 200 gm.* cod liver oil.

103. **The Sympathetic Nervous System and Intestinal Intoxication.**—Hirschfeld believes that the disintegration products of albumin metabolism circulating in the blood stimulate the sympathetic nervous system and bring about a condition of hypertonicity which manifests itself in the *clinical symptoms* of intestinal intoxication. He applied the epinephrin test of the eye in 265 cases, twenty of them with intestinal intoxication, and found it positive in all these twenty cases. He gives in brief nineteen case-histories showing the parallelism between the severity of the intoxication and the tonus of the sympathetic system.

105. **Cerebral Paralysis after Diphtheria.**—Dynkin describes two cases of unilateral hemiplegia following diphtheria, and gives an extensive review of the literature of the subject. These paralyses occur only after very severe forms of diphtheria. *In all cases physical signs of heart failure* are manifest, such as arhythmia, murmurs and dilatation. They occur mostly in the third or fourth week of the disease. A paresis of the facial and hypoglossus nerves and aphasia are generally observed in conjunction with them. In many cases there are also peripheral disturbances, such as paralysis of *the soft* palate and of accommodation, failure of patella reflex and incontinence of urine and feces. The cause of postdiphtheritic *hemiplegia* is generally an embolus from heart thrombosis: much more rarely thrombosis of the cerebral vessels.

Medizinische Klinik, Berlin

117 Chemistry of the *Protoplasm* and Nuclei of the Cell. R. Muschler.

111. **Tuberculosis of the Skin.**—Jadassohn has had *extensive* experience with roentgenotherapy, the *two-route treatment,* and all other *modern* methods *of treating* tuberculous

invasion of the skin, and has found roentgenotherapy remarkably effectual in many cases so that surgical measures have been more and more restricted of later years. But when the mucous membranes are involved, the actual cautery still seems to give the best results attainable. He is convinced that too timid dosage of the Roentgen rays has caused lupus cancer to be more prevalent than it would be without it. He insists in conclusion on the importance of practitioners recognizing tuberculous skin lesions when they first appear, so that treatment can be applied in time to render it promptly effectual. The ordinary skin diseases of children should be kept clean and healed up as soon as possible, and it should be borne in mind that everything useful in the prophylaxis of pulmonary tuberculosis has its place also in warding off tuberculosis cutis.

112. **Management of Gout.**—Garrod declares that the greatest progress in this line in recent years is the recognition of the important part played by uric acid in metabolism and the discovery that a diet can be arranged which is almost free from purins and yet contains plenty of albumin: milk, eggs and cheese are particularly useful on this account. But he emphasizes that the diet is not everything in the management of gout; moderation in all things, not merely in eating and drinking, is the golden rule by which the gouty are kept free from attacks. Avoidance of fatigue and of even the slightest trauma and everything liable to upset the precarious balance is the key to success. He had a patient develop an attack after mere removal of ear wax; another has an attack whenever he takes a long railroad ride.

115. **The Albumin Reaction in the Sputum.**—Schmitz examined the sputum from 100 patients and states that his findings sustain the importance of this welcome addition to our means of diagnosing pulmonary tuberculosis. He found albumin in the sputum in nearly every case of beginning pulmonary tuberculosis long before tubercle bacilli could be detected. At the same time the reaction was negative in some cases of manifest tuberculosis. The negative cases seemed to be those with a tendency to proliferating cicatricial changes, while albumin was present in all the cases of the inflammatory exudation type. (Application of the test for quantitative estimation was reported in The Journal, Oct. 26, 1912, p. 1537.)

118. **Why Living Tissue Is Not Digested by Its Own Juices.** Kawamura's research seems to establish the presence of an antipepsin in the circulating blood which prevents the gastric juice from digesting the stomach walls. Only when there is some interference with the blood-supply, shutting it off from a certain area, is the corroding juice able to exert its destructive action on the tissues. A gastric ulcer is thus primarily the result of shutting off part of the blood-supply from the wall of the stomach at this point.

119. **Neurotic Duodenal Ulcer.**—Westphal and Katsch report from von Bergmann's clinic at Altona thirty cases of duodenal ulcer confirmed by operation or necropsy, calling attention to the varying clinical picture in this material. The presence of the ulcer keeps up a constant irritation of the vegetative nervous system, and this may manifest itself at points remote from the actual seat of the ulcer. Most of the symptoms are the work of the secondary gastric neurosis, and the fluctuations in the neurosis are responsible for the objective findings and for some of the symptoms and subjective disturbances. The peculiar tenacity of the neurosis is due, they think, to the anatomic lesion which prevents the vegetative system from getting any rest or regaining its balance. Treatment should be directed against both the neurosis and the anatomic lesion. Atropin will aid in combating the neurosis by modifying the innervation; by thus aiding to correct the correlated neurosis, it will break into the vicious circle and, by setting the ulcer at rest, aid in its healing. Internal treatment along these lines is peculiarly beneficial when the stomach troubles are of purely neurotic nature and secondary to the duodenal ulcer. The treatment otherwise for both duodenal and gastric ulcers should be along the same lines, resting and sparing the organs as much as possible. The anatomic lesion may be combatted by direct surgical intervention or indirectly, by transforming the abnormal muscle functioning. By putting an end to the constant irritation from the ulcer, the vegetative nervous system will gradually have its balance restored and the neurotic symptoms will consequently subside. A direct operation on the ulcer is indicated only after failure of systematic and long continued internal treatment or when there is hemorrhage or perforation. The neurotic element in duodenal ulcer disturbances causes the clinical picture to vary in different cases so widely that it is more than probable that the primary ulcer has not been recognized in many such cases. The neurosis may affect the motor functioning or the secretory functioning. In the former, the clinical picture is that we are accustomed to with gastric hyperacidity; in the excessive-secretion form, the clinical picture is that of true Reichmann's disease. They compare two cases to illustrate these types: One had pain only when the stomach was being evacuated; the other the hunger pain exclusively at night. One had no vomiting; the other vomited frequently. One had constant tenderness at the "duodenal point;" the other never had tenderness here. One had moderate hyperacidity; the other extreme hyperacidity and parasecretion. The stomach in one was excessively tonic, with extreme hypermotility; in the other the stomach was hypotonic and stretched, with only weak peristalsis. The duodenum bulged in one; the pyloric region with the spasm of the pylorus in the other. The stomach in one hastily expelled its contents, at least at first, while the other patient had retention of stomach contents over six hours.

The distinguishing characteristics of the two types may be expressed by the terms "hyperperistaltic duodenal ulcers" and "maximal-secretion duodenal ulcers." The common features of the two types are that the patients have had gastrointestinal disturbances off and on for years, with periods of entire subsidence of all trouble; both have a circumscribed area of tenderness, one at Boas' right tender point and a history of tenderness over the duodenum although not to be elicited at present; the other with constant tenderness over the duodenum. Both have a tendency to hypersecretion in the stomach although with wide difference in the degree. Both have other signs of derangement of the vegetative nervous system, and in neither of the two typical cases contrasted above had there been any known bleeding. The operation first confirmed the presumptive diagnosis of a duodenal ulcer.

Much research work is being done at this clinic on the regulators of the intestinal tract and peptic ulcers of spasmogenic origin. Spasmodic contraction of the smooth muscle seems to be the cause of the pains with peptic ulcer and possibly may be the primary cause of the ulcer itself. A recess casting a shadow in the duodenum is not only pathognomonic of duodenal ulcer but it confirms that it has bored into the tissues. Another typical finding is the continuous retention of the bismuth suspension in the upper part of the duodenum, the *Dauerbulbus duodeni*, especially when the duodenum here is distorted. Almost every detail in the history and present status of a duodenal ulcer case occurs likewise with merely a gastric ulcer, confirming anew the importance of the element of neurosis. The thirty cases are analyzed in detail.

120. **Aneurysm of Cerebral Arteries.**—Reinhardt reviews ten cases, five in women between 30 and 58, five in men between

18 and 72. In four cases a congenital predisposition was evident and in three others probable; in two syphilis was responsible. The aneurysms were quite small except in one case in which the very large aneurysm simulated a malignant tumor in the sella turcica; it had induced symptoms for nine years, gradually growing more severe. At the operation the bleeding was assumed to be of the venous type owing to the anatomic conditions; the fact that an artery was involved was not recognized until too late.

121. **Artificial Respiration.**—Liljestrand reviews the history of artificial respiration and states that the results of rhythmic compression of the chest are not very encouraging. Better methods than this for artificial respiration are urgently needed; and he thinks that the pulmotor or Meltzer's method of intratracheal insufflation should be more generally available and applied. The rhythmic compression methods do not supply adequate ventilation for the lungs but may advantageously supplement the Meltzer method, at least.

123. **Gouty Arthritis.**—Jacobsohn gives a number of illustrations of the Roentgen-ray findings in eighteen cases of uric acid arthritis, all showing that the deposits have a destructive influence on the bone beneath. This suggests the advisability of removing gouty tophi to prevent further injury of the joint. In many instances roentgenoscopy alone cleared up the diagnosis when the clinical picture was apparently merely ordinary chronic rheumatic arthritis; in other cases the diagnosis of gout was not confirmed by roentgenoscopy. The findings with the latter should be weighed in connection with the metabolic findings.

126. **Treatment of Abortion.**—Mihalkovics and Rosenthal had 1,147 cases of abortion between Jan. 1, 1910, and June 30, 1912, with a mortality of 0.5 per cent., all being cases of beginning or incomplete abortion. In the last 100 cases bacteriologic examinations were made. They found microorganisms in every case, and in many cases several kinds. In all but one case there were pathogenic bacteria of some kind. In eighty-five cases staphylococci were found. They believe treatment should be based on clinical symptoms and not on bacteriologic findings; 875 patients were given active treatment and 272 expectant. Active treatment generally consisted in dilating the cervix with tampons and emptying the uterus with the finger; only in cases in which it was necessary, dilatation by Hegar's method and curetting. They prefer the active to the expectant treatment not only because it yields better therapeutic results but because it meets the economic needs of the patients by enabling them to return to their work sooner.

128. **Final Results of Obstetric Operations.**—Schröder found from a study of statistics for the years 1893-1905 at Bonn that of the children delivered by cesarean section and induced premature labor, fully one-half, possibly more, were dead before the end of the first fifteen months. This large mortality is partly due to the operation, partly to the fact that the economic situation of the parents is such that they cannot properly care for the infants, who need more than ordinary attention. Schröder believes that in view of this heavy mortality, of the hardships inflicted on parents and child, and the prolonged inability of the mother to work following the obstetric operation, it would in many cases be preferable to perform a mutilating operation on the child, unless the parents especially desire the maternal operation.

129. **Hypophysis Treatment.**—Hofstätter finds that except where overdoses have been given there have been no bad results from administration of hypophysis extract aside from some unpleasant, but not serious nervous manifestations. No injury to the kidney has ever been demonstrated. It should be given with caution to persons with uncompensated heart lesions or severe arteriosclerosis and to very nervous patients. The chief difficulty in its administration, he remarks, is that there is no standardized preparation which makes it possible to give an accurate dosage of the physiologically active substances.

130. **Abnormally Large Infants at Birth.**—Hübner says that infants over nine pounds in weight are born in over 3 per cent. of deliveries. A weight of over thirteen pounds very rarely occurs. He discusses at length the medicolegal bearing of the question as to whether abnormally long gestation can be given as a reason for the development of a large fetus. He concludes that the legal limit of 302 days safeguards the interests of illegitimate infants.

132. **Women in Industry and Women's Diseases.**—Hirsch calls attention to the increasing participation of women in industry in all countries. The percentage of women engaged in gainful pursuits varies from 42.8 per cent. in Austria to 8.4 per cent. in Russia. This entails on women the double burden of industrial labor and motherhood, to which is often added that of household work. He gives statistics showing the number of women engaged in various industries in Germany. Bad hygienic conditions and overwork affect women more severely than men. Among 10,000 working men from 25 to 34 years of age the yearly mortality was 492; that among an equal number of working women was 601, although the mortality for women in homes of the same social classes was about the same as for men. Tuberculosis is especially prevalent among women working in tobacco factories and printing establishments; also among workers in glass factories, from inhalation of dust. Anemia and chlorosis are frequent among workers in the textile trades and in all places where air and light are deficient. All these diseases have disastrous secondary effects on pregnancy and labor. Abortions are about seven times as frequent among employed as among non-employed women; premature births six times; placenta praevia, hemorrhage, pernicious vomiting and extra-uterine pregnancy two and a half times, pathological puerperium lasting more than thirteen weeks, five times.

Lead poisoning has a particularly active effect in producing abortions. It has been found in the organs of the fetus, and children of women working in lead show a special tendency to epilepsy, paralysis and hydrocephalus. Overwork also causes secondary diseases of the generative organs, especially in young girls who go to work at 13 or 14, at about the time menstruation is being established. Physicians, and more particularly women physicians, have before them the social task of seeing that the law provides adequate protection for women in industry.

134. **Physiology of the Hypophysis.**—Schlimpert tried to determine from experiments on cattle whether there was any change in the hypophysis during pregnancy. The essential principle of the gland does not seem to be present in greater

quantity in the pregnant than in the non-pregnant animal. It can be demonstrated in embryos of cattle at the tenth week by its vasoconstrictive action, and from the twenty-eighth week also by its effect on respiration.

138. Exophthalmic Goiter and the Genital Organs.—Lampé believes that Basedow's disease is caused by a disorder of the branchiogenous organs, including the thyroid, due to embryonic predisposition. This abnormal function brings about a secondary disorder of the genital glands, which are antagonistic to the thyroid in their action.

139. The Phagocyte Index.—Stuber and Rütten remark that the opsonic count has not made much headway in Germany; there is a general distrust of the hypothetic opsonins while the technical difficulties are great. They have worked out a very simple method for the phagocyte count which throws light on the vital functional capacity and behavior of the leukocytes. Instead of trying to determine the phagocytic capacity of the leukocytes in regard to the special germs responsible for the trouble in the individual case, they sought to determine the vital capacity of the leukocytes in the individual case as tested with a standard object to be phagocyted. After many tentative experiments they found the spores of the thrush fungus, *Oidium albicans*, apparently the best adapted for the purpose. It is cultivated on glycerin-agar with 0.25 or 0.5 per cent. eosin on which it develops without filamentous threads, running only to spores during months of cultivation. A culture of this fungus is suspended in an artificial serum (7.5 c.c. sodium chlorid; 6 c.c. sodium citrate and distilled water to 1,000 c.c.). The leukocytes are liable to clump unless there is some homogeneous serum or ascitic fluid present or other solution of albumin. They found a saturated aqueous solution of egg albumin best for the purpose. In a centrifuge tube are placed 0.1 c.c. of the artificial serum; 0.1 c.c. of the ovalbumin solution; 0.03 c.c. of the suspension of the thrush fungus, and 0.03 c.c. of the blood to be examined. The contents of the tube are well mixed with a platinum needle and the tube is then kept for forty-five minutes at 37 C. It is then centrifuged for one minute with about 800 turns. Most of the red corpuscles are then in the tip of the tube, above this comes a layer of leukocytes, and above this the serum. The serum is then aspirated out: the long drawn out tip of the tube, containing the red corpuscles, is then broken off. The leukocytes are thus left in the tube and they are easily blown out on an object glass and stained by Leishman's technic. The thrush fungus spores take a bright blue and are encircled with a white halo. They count the number of spores in 200 leukocytes; with normal phagocytes there will be 200 spores in 200 leukocytes, so the index will be $\frac{\text{Number of spores}}{\text{Number of leukocytes}} = 1$. This is the standard index in health. The individual index is the $\frac{\text{Patient's index}}{\text{Normal index}} =$ Phagocytic Index. The whole technic is thus extremely simple and in the cases cited the low index at the height of the disease and its gradual rise during convalescence amply demonstrate how the phagocytic index mirrors the capacity and power of the organism to combat invading infection. Among the important information which it affords may be mentioned the differentiation of gastric ulcer from gastric cancer as the phagocytic index shows that the organism is not depressed by malignant disease. The index varies in health from 0.8 to 1.2; when it is merely 0.5 the defensive forces are evidently at a low ebb. Of course it is a delicate biologic reaction, and it is necessary to test the fungus spores occasionally with normal blood to detect degeneration.

140. Compression of the Lung by Separating it from the Chest Walls with or without Filling up the Space Left.—Baer and Jessen each present a contribution to this subject, reporting clinical experience which encourages further work in this line. Baer's method is to detach the pleura from the ribs and fit into the extrapleural space thus made a paraffin filling. For each 75 c.c. of paraffin with a melting point at 58 C., he adds 25 c.c. of paraffin melting at 50 C. and 1 gm. bismuth and a little mild disinfectant. This is thoroughly blended and with a knife chunks of the jelly-like mass are fitted into the extrapleural space and the skin is sutured at once. He has thus treated two patients, as he describes at length with the necropsy findings in one who had fatal tuberculous meningitis seven weeks afterward. The cavities were found entirely obliterated and scarcely recognizable. The experiences related seem to demonstrate the harmlessness of the method in comparison with resection of ribs; the necropsy findings show that the filling heals without inflammation. There is no danger of aspiration while expectoration was promoted from the very first, and the amount of sputum dropped from 150 to 50 c.c. and from 130 to 15 c.c. in a remarkably short time. There is merely a linear scar left while the chest retains its normal outline. The great advantage of Baer's technic is that the compression by the extrapleural pneumolysis and filling is applied exactly at the point where it is needed, not over the whole lung as with an artificial pneumothorax with which the sound parts of the lung as well as the diseased are compressed.

Jessen reports similar experiences only he found in the course of the six cases in which he has applied pneumolysis that the filling is not necessary; the desired results are attained without this. Adhesions sometimes interfere with the success of the pneumolysis, just as with making an artificial pneumothorax, but when it succeeds the effect is as good as with excision of ribs without the shock of the latter and the resulting disfigurement. If the lung can be detached sufficiently more or less all around no filling is necessary. If a filling is required he prefers a mixture of equal parts of white wax and white vaselin, with 0.5 per cent. magnesium carbonate and salicylic acid; this is absorbed more slowly than Baer's paraffin mixture, he says. A piece of a rib is resected and the finger is worked between the periosteum and endothoracic fascia and the lung detached. In his first case a young man had a cavity in each upper lobe with pleuritic adhesions. After resection of 3 cm. of the second rib on the left side, the apex and upper lobe down to the fourth rib were detached and 200 c.c. of the wax-vaselin filling injected. No effect on the sputum was observed. Three weeks later the lung on the other side was detached except for a cord-like adhesion fastening it to the first rib. No filling was injected on this side, but at once the sputum dropped from 50 c.c. to 10. In another case 300 c.c. of paraffin were injected after the pneumolysis; the eighth day the region protruded and the paraffin was forcibly expelled, with fluid, the whole resembling a delivery. There was no febrile reaction, the parts soon healed, and the sputum dropped from 50 c.c. to 15 and the patient seemed transformed, all toxic symptoms subsided and roentgenoscopy shows the large cavity collapsed as completely as after thoracoplasty. Two other cases show that adhesions may interfere to prevent a favorable outcome, and resection of several ribs to mobilize the chest wall may be the only resource. In all the cases there was a rise in temperature after the pneumolysis, the manipulation of the lung evidently forcing toxins into the circulation.

EPIDEMIC STREPTOCOCCUS SORE THROAT —ITS SYMPTOMS, ORIGIN AND TRANSMISSION *

JOSEPH A. CAPPS, M.D.
CHICAGO

Epidemics of streptococcus sore throat have recently sprung up as a scourge, so new that they receive no mention even in the latest editions of our text-books.

Within two years three extensive and alarming epidemics have occurred, which have no counterpart in American medical history. In some respects they call to mind the first severe invasion of influenza, but the latter disease spread everywhere throughout the country, whereas each of the streptococcus sore throat outbreaks was confined to a single community.

It is quite probable, however, that many of our local tonsillitis epidemics, loosely designated as "grip," have in reality been due to streptococcus.

In England comparatively small outbreaks of "septic sore throat" have been described[1] in seventeen localities, and a probable relationship to the milk-supply has been recognized; but in few instances were careful bacteriologic investigations carried out. The streptococcus was first demonstrated in cultures obtained from cases of sore throat in Finchley (1904), where 550 persons were attacked. The *Streptococcus pyogenes* was first detected in the suspected milk in the Guildford outbreak (1903). The following year in the Colchester epidemics, claiming 600 victims, the streptococcus was obtained both in the throat exudate and in the milk. This organism was likewise recovered from the throat and the milk in the Christiania epidemic of 1908, in which 548 persons fell a prey to the disease.

The existence of mastitis in the cows was noted in all four of these foreign outbreaks.

The American epidemics of streptococcus sore throat were carefully studied from a clinical and bacteriologic point of view, and many new facts bearing on the etiology were brought to light. A brief summary of the salient features of these outbreaks may be profitable.

Extent of Epidemic.—About 1,400 persons were stricken in the Boston outbreak, and of this number 1,043 were investigated. In Baltimore about 1,000 were affected and 602 recorded. The total in Chicago was estimated to be over 10,000, though only 1,271 were studied.

The Organism.—In all three cities a peculiar type of hemolytic capsulated streptococcus was secured from throat cultures or from the peritoneal exudate of fatal cases. Davis compared cultures from each outbreak and found them practically identical.

Season.—The cases appeared in the winter and spring months, occurring in Chicago during the last of December and in January, in Baltimore during March, and in Boston during May.

Explosive Outbreak.—A sudden appearance of a large number of cases was characteristic of each epidemic. Often several members of a household were taken ill almost at the same time, suggesting a common source of infection rather than dissemination by personal contact.

Clinical Symptoms.—The sore throat manifestations were similar in all epidemics. Intense hyperemia with or without a grayish exudate was the usual picture.

Enlargement of the cervical lymph-nodes was one of the most characteristic symptoms, occasionally resulting in suppuration. Extreme prostration and a tendency to relapse were emphasized by most observers.

The three epidemics reveal a striking similarity in the complications. Otitis media, peritonsillar abscess, erysipelas or some other form of skin eruptions and nephritis were common sequels. Arthritis, endocarditis and myocarditis occurred in many cases. Pleurisy and pneumonia often ushered in a fatal septicemia. But the most dangerous and remarkable complication was peritonitis, which was responsible for a great number of deaths.

Relationship to Milk.—The infection was traced definitely to a single milk-supply in every city. The sore throat cases traced to one dairy made up 70 per cent. of the total in Boston, 65 per cent. in Baltimore and 72 per cent. in Chicago. As the suspected dairy in each instance supplied only a small proportion of the city consumption, these percentages become highly significant. There is no doubt that secondary cases developed by means of contact, but it quite overturns our accepted theories of transmission to observe that the secondary contact cases were few compared with the number of cases directly infected by the use of milk.

As this fact was established in all the epidemics we must in the future revise our notions concerning the importance of contact in the dissemination of streptococcus infections.

Ultimate Sources of Contamination.—The indictment in each of the epidemics against a single dairy as the carrier of the germs was so strongly supported by clinical facts as to be final and conclusive.

The evidence submitted to show when and how the milk became infected may be considered under the following classification:

1. Streptococcus in the mixed milk at the collecting plant or at the farm.
2. Mastitis in cows, from whose udders streptococcus is directly obtained.
3. Streptococcus sore throat in the milkers.

---

* Read in the Section on Pathology and Physiology of the American Medical Association, at the Sixty-Fourth Annual Session held at Minneapolis, June, 1913.

[1] Savage, W. G.: Milk and the Public Health, Macmillan & Co., London, 1912

4. Streptococcus sore throat in other employees who handle the milk.

In his study of the Boston epidemic, Winslow[2] found no evidence of cattle disease and no well-defined cases of sort throat in a milker. He did discover, however, cases of sore throat in employees at the farm and dairy. The actual infection he attributed to a human carrier.

Stokes[3] succeeded in obtaining more definite information in the Baltimore outbreak. He found the streptococcus epidemic in the raw mixed milk of one herd but could not trace the infection to the cow. There was no history of septic sore throat cases among the farmers or employees. Although final proof was lacking, Stokes expressed the belief that the infection originated in the cows.

Investigations in the Chicago epidemic revealed the *Streptococcus pyogenes* in the milk obtained directly from the inflamed udder of the cow and also in cultures taken from a milker with sore throat. A history of septic sore throat among employees was also established.

Direct contamination of the milk by human carriers does not offer a satisfactory explanation of these epidemics, because such a contamination is likely to be casual and occasional, whereas the outbreaks indicate a continuous infection for a few weeks. Furthermore, the amount of infectious material introduced by a human carrier in coughing, etc., is relatively small to produce such appalling results.

A mastitis infection with streptococcus, on the other hand, would entirely explain the continuous stream of milk contaminated with enormous numbers of organisms.

A comparison of the American epidemics does not indicate at first glance that the source of infection was the same, because mastitis was not found at all in the Boston herds, and only a non-pathogenic form of garget was discovered in Baltimore.

These apparent discrepancies, however, may be cleared up by recent investigations. Davis[4] has succeeded in producing in the udder of a healthy cow an infection with a human strain of *Streptococcus hemolyticus*. The germs, introduced through a slight abrasion of the teat by the contaminated hand in the act of milking, caused an ascending infection of the teat and udder, characterized by the presence of pus and myriads of streptococci that persisted for two or three weeks. Strange to say, there was no caking of the bag. We cannot therefore place any dependence on caked bag as a necessary accompaniment of mastitis. Streptococcus mastitis without caking may well have existed in some of the cows in the Boston or Baltimore herds and yet have escaped detection.

In the future, it will be necessary to examine the milk from each cow in a suspected herd for pus and streptococci.

I believe that streptococcus mastitis will be recognized as the most important source of extensive epidemics of septic sore throat. That the mastitis may originate by transmission of human streptococcus through the medium of the milker seems to be established. Whether or not mastitis due to a specific bovine streptococcus may become virulent to man is a problem yet to be determined. When we come to a consideration of prophylaxis all other measures and precautions sink into insignificance when compared with thorough pasteurization. A general enforcement of pasteurization would put an end to a malady that otherwise promises to be one of the most formidable and wide-spread of the infectious diseases.

122 South Michigan Boulevard.

CHRONIC STREPTOCOCCUS ARTHRITIS*

DAVID J. DAVIS, M.D.

CHICAGO

The relation of streptococci to arthritis is a very broad one. The highly acute purulent inflammation of joints which may be simply part of a general streptococcus pyemia or septicemia is well known and fairly well understood. It occurs in connection with severe streptococcus infections, such as puerperal fever, infected wounds, erysipelas and common infectious diseases. Of the latter I shall mention especially septic sore throat as it has been observed by Capps and others in connection with milk-borne epidemics. In all of these there is a tendency, at times not very marked, but at other times striking indeed, for the streptococci to produce arthritis.

The tendency on the part of streptococci to localize in joints of experimental animals seems to concern the several varieties, though to an unequal extent. The common hemolytic streptococci and the *Streptococcus mucosus* readily attack joint cavities; the *Streptococcus viridans*, on the other hand, rarely does so. The *Diplococcus rheumaticus* is also very prone to attack joints as shown by Poynton and Payne, Beattie, and especially by Rosenow's recent work. The streptococcus found in septic sore throat, which appears to be a highly virulent variety of the hemolytic streptococcus, readily produces multiple arthritis in animals with often other lesions such as endocarditis, pericarditis, myocarditis, peritonitis, etc. This agrees with the occurrence of the serious complication in human beings observed during these milk-borne epidemics.

The subacute or chronic types of arthritis leading toward some permanent change in the joint or periarticular structures form a large and miscellaneous group of joint disorders, and their classification is as yet imperfect and unsatisfactory. "Arthritis deformans" is, perhaps, the term most commonly applied to them. Their etiology is undoubtedly manifold and they probably furnish an illustration in which similar and often indistinguishable pathologic changes and clinical symptoms are brought about by widely different agents. From this large group in recent years, however, certain smaller groups have been separated; for example, traumatic arthritis deformans and certain cases of gonococcal arthritis. In other words, as soon as the true etiology of a case, or group of cases is discovered it is removed from this large group of arthritis deformans to a class or group designated by its etiologic agent.

In this paper I wish to discuss chiefly from an etiologic point of view a certain group of these cases of chronic arthritis or arthritis deformans whose cause can with fair definiteness be attributed to a streptococcus infection, usually though not always originating somewhere about the upper respiratory passages. I believe that it is often possible to separate these cases clinically and especially by the history from deforming arthritides of other origin. Etiologically also I believe that these cases can and should be at present placed in a group by themselves and removed from the larger and more miscellaneous group of arthritis deformans.

* Read in the Section on Pathology and Physiology of the American [illegible] at the Sixty-Fourth Annual Session held at [illegible]

* From the Pathological Laboratory of St. Luke's Hospital, Chicago.

The clinical symptoms of these cases, though often indefinite, still possess certain features which are more or less characteristic. It has been common to speak of an acute and a chronic form or type of deforming arthritis. This is done, for example, by McCrae in his excellent article on this subject in Osler's "System of Medicine." The chronic form in general tends to progress slowly and gradually without definite exacerbations or recurrences. The more acute or subacute form often has a rather sudden onset with some fever and involvement frequently of several joints. Such attacks tend to subside and recur, often closely resembling acute articular rheumatism, with which I believe it is not uncommonly confused in the early stages. The joints may be red, swollen, painful and tender; or the attacks may be light and the patient may experience only slight and transient pains and perhaps some stiffness in the joints. In contrast with acute rheumatic fever, salicylates have little or no effect, especially early in the disease.

The striking feature in these cases, however, is the persistence of the symptoms and the tendency to more or less permanent change in the joints. This is the chief differentiating feature from acute rheumatic fever. Not uncommonly heart murmurs and distinct endocarditis may develop in these cases during or following the recurrences. In common with acute articular rheumatism is the fact that the attacks and exacerbations are often preceded or appear simultaneously with an attack of tonsillitis or pharyngitis. An infecting focus may appear in other parts of the body, but the pharyngeal ring seems to be by far the most common atrium.

The history of tonsillitis in these chronic cases just preceding or simultaneous with the onset is of great importance in the diagnosis and may be sufficient in itself to determine how the case should be managed. I wish again to emphasize, however, that border-line cases are common and it is difficult or impossible at times to determine whether or not they belong to this group. Furthermore, the occurrence of a focus such as diseased tonsils or infected teeth and arthritis in the same person does not necessarily mean that the processes are directly related. They may or may not be.

A report[1] has already been made on the bacteriologic and pathologic study in some of these cases, and here I wish to present further data more especially on points which concern the specificity of streptococci as causative agents.

I have had an opportunity to make observations in forty-two cases which I think may be placed in this group of arthritides and in which the atrium of infection appeared to be in diseased tonsils. Other cases of chronic arthritis have been observed and studied in which the atrium apparently was in other locations, such as the teeth, urinary tract, etc., but these I do not wish to consider at this time. In all the cases with one or two exceptions the tonsils were removed and cultures made from the crypts. From thirty-eight a hemolytic streptococcus was grown and in the great majority in practically pure cultures. A point that I wish to call especial attention to is the occurrence of these cocci in the crypts often to the exclusion of other bacteria. To demonstrate this, careful cultures must be made from the depths of the crypts after the tonsil has been incised with a sterile knife. Surface cultures or cultures made from badly lacerated tonsils give usually many buccal cocci chiefly of the *Streptococcus viridans* type.

In some of the patients joint effusions appeared at some time during the course of the disease. In four patients careful examination of the aspirated fluid in smears and cultures revealed no bacteria of any kind. Leukocytes were few in number. Blood-cultures made in ten cases did not yield positive results. These data are in agreement with the reports of many other workers on this subject. This does not mean that bacteria may not be found at times in the blood or that the bacteria may not be constantly present in or about the joints. As animal experiments show, the exudate especially in old joint lesions is often sterile so far as cultures indicate. On the other hand, smear preparations carefully made may show a few cocci.[2]

The tonsils in these cases may or may not be enlarged. While usually they are somewhat hypertrophied, often they are small and at times submerged. The latter are dangerous because they are easily overlooked. Proper drainage in such organs is naturally interfered with. The color is often diffusely red or bluish-red; at times large hyperemic areas appear. On slight pressure there may be a purulent exudate from the crypts consisting of pus cells and diplococci. It should be stated also that in some patients there is nothing in the appearance of the tonsil to make one suspect a pathologic condition. In a number of cases the tonsils had been at some previous time only partially removed or sliced off with a tonsillotome. Such operations are not only not effective but are positively harmful on account of the formation of fibrous tissue at the cut surface which tends to occlude the crypts and prevent drainage.

Microscopic examination of the tonsils usually reveals clusters of polynuclear leukocytes in the crypts and especially in the epithelium lining them. At times infected foci occur beneath the epithelium and small abscesses may appear in the tissue. The blood-vessels may be hyperemic, and plasma-cells about vessels and beneath and in the epithelium are always present.

The streptococci cultivated from the diseased tonsils have been carefully studied. Not all are identical, but they evidently belong to the general group of hemolytic streptococci.

Most of these organisms have a moderately wide, clear zone of hemolysis on blood-plates, though there is considerable variation in the width of zone. The colonies are small and gray and have little tendency to spread. They are not mucoid or watery, and the cocci are not encapsulated. They do not ferment inulin, and some ferment mannite and others do not. None ferment raffinose and their reaction on lactose is not constant; most of the strains ferment it; a few do not.

Some of the streptococci found in certain cases have a much narrower zone of hemolysis which also may be slightly grayish or turbid. The margin is less distinct and the colony smaller. The difference between this and the first streptococcus mentioned is sufficient to enable one to separate them, especially when they occur on the same plate. Morphologically the cocci are perhaps slightly smaller and as a rule, though not always, form shorter chains than the other streptococci. They may produce arthritis when injected into animals in large doses, but they are as a rule not highly virulent. They were found in a number of cases associated with the more hemolytic variety and sometimes they appeared practically pure. While often the differentiation of the two kinds is clear this is not always so, and not infrequently intermediate or transition forms were seen.

---

[1] Davis: Jour. Infect. Dis., 1912, x, 148.

[2] A careful study is now being made both in animals and in man with a view to clear up the point as to the presence of cocci in or about chronic arthritic joints. A hemolytic streptococcus has already been cultivated from the synovial membrane obtained from a case of chronic arthritis in which Dr. McArthur operated. This organism readily produces arthritis in rabbits.

When the streptococci are injected in sufficiently large doses (one or two blood-slants) intravenously into young rabbits, they invariably localize in or about the joints, producing as a rule multiple arthritis. This condition has been produced in over two hundred animals. In a sense the cocci are not highly virulent, large doses (several tubes) being necessary to kill guinea-pigs by intraperitoneal injections. The joints most commonly affected in the animals are the wrists, phalanges, knees and ankles, though practically every joint in the body is at times involved. The infection in the joints usually appears a few days after inoculation and continues for from one to three weeks or longer. Relapses may occur. Not infrequently the changes in the joints become chronic with considerable deformity, and with the formation of exostoses, lipping of margins and other hyperplastic changes. At times such animals live for many months, becoming badly deformed and crippled and ultimately dying in an emaciated condition.

Early in the course of the infection in these animals, cultures from the joints usually yield streptococci. They tend to disappear and at times even after the second or hird day no growth may be obtained. In the chronic oints after weeks or months the streptococci may still e found in the exudate, though often they are not. The xudate early is slimy, mucoid and glairy, later becomng more purulent. In very old joints it may be gelatnous in character.

In about 10 per cent. of the animals so inoculated definite endocarditis results. Also occasionally a ibrinous pericarditis is seen (observed five times). A areful histologic study of these joints and the heart esions have been made by Dr. Leila Jackson[3] in the athologic laboratory of St. Luke's Hospital. In the eart muscle Jackson often finds focal lesions consistng of clusters of round cells and, in older lesions, of eculiar large giant-cells. In these nodules cocci may e found especially early, in large numbers. A striking eature of these lesions is the relative absence of a egional leukocytic infiltration. Jackson likewise finds eculiar and characteristic nodules in the periarticular tructures and in the synovia. The bacteria enter the oint cavities as early as ten hours after intravenous njection apparently from the rich meshwork of synovial apillaries in the lateral plicae. In the ends of the ones, especially about the epiphyseal cartilages, at imes definite infarcts due to bacterial emboli are seen extending toward the joint, usually subjacent to the periosteum. These experimentally produced lesions in animals bear certain resemblances to lesions described by other writers in the heart and joint structures of man in cases of acute rheumatic fever.

It should be pointed out that hemolytic streptococci may occur in the crypts and on the surface of tonsils not only in ordinary streptococcus tonsillar infections but also in normal tonsils. These streptococci often cannot be distinguished from the streptococci found in the tonsils of those patients suffering with joint trouble. Consequently the presence of streptococci in cultures should be carefully interpreted. They may or may not be significant, just as finding pneumococci in the throat or sputum may or may not be significant for the diagnosis of lobar pneumonia.

I shall refer to the therapeutic side of this subject largely on account of its bearing on the etiology as manifested by the "constitutional reactions" following extirpation of infected foci and the administration of autogenous vaccines. In this group of forty-two cases there was an opportunity to follow nearly every patient for a considerable period of time. As generally conceded now by those who have had most experience, the value of focal extirpation is unquestioned. The observations of Dr. Billings, who saw many of the cases here reported, may be referred to. In nearly every patient in this series marked improvement appeared and often complete cure resulted from the enucleation of the tonsils. The recovery was gradual as a rule. Naturally marked bony ankylosis and extensive fibrous change could not be essentially altered or modified. In about one half of the cases vaccines were prepared from the streptococci isolated from the infected focus. On the whole, the progress of cases so treated seems to indicate that the improvement is hastened by the use of these vaccines.

In some patients the vaccines acted like a specific. As an illustration let me cite an instance. A patient (case of Dr. Arthur Elliot) had suffered for the past three months with severe and progressive arthritis involving many joints of both upper and lower extremities and certain vertebral joints. The trouble began with an attack of sore throat and simulated in some respects acute articular rheumatism. Blood-culture was negative, leukocytes 11,400. The tonsils were removed and found pathologic. Cultures carefully made from the crypts of both tonsils gave an absolutely pure growth of hemolytic streptococci. An autogenous vaccine was prepared and 200 million were given in the first dose. Eight hours later the patient reacted rather sharply and severely. He felt chilly and there was a degree or two of fever. All the involved joints became distinctly more tender and some were swollen. This condition lasted for about two days, and then subsided rather rapidly. With this there was marked improvement in the patient's condition. At five-day intervals three doses of vaccine were given and in about two weeks or less the joints had assumed almost their normal condition.

In a number of instances this prompt reaction or hypersusceptibility after relatively small doses of dead autogenous streptococci has been noted, and it corresponds undoubtedly with the reaction that has been observed in other infections, for example, by Irons in gonorrheal arthritis after injections of gonococci. Not all cases by any means show it. I think that in those that do the improvement on the whole is more prompt and rapid. Attention is here called to the fact that this reaction would seem to be conclusive proof of the specificity of the streptococcus in such arthritides.

Another point of interest is that in three instances acute attacks or exacerbations followed the tonsillectomy almost immediately. This phenomenon has been noted occasionally by many observers and is undoubtedly due to a dissemination in the circulation of infectious material by the operation. This is another argument in favor of the arthritic process being infectious and located primarily in the tonsils.

The value of vaccines was also demonstrated in one case in which it was impossible to remove the diseased tonsils on account of high blood-pressure. The man had a very serious chronic polyarthritis for nearly a year.

---

[3] Jackson, Leila: Experimental Rheumatic Myocarditis, Jour. Infect. Dis., 1912, xi, 243. Experimental Streptococcal Arthritis in Rabbits. Ibid., 1913, xii, 364.

The joints were swollen, stiff and painful. A hemolytic streptococcus was isolated from material obtained from the tonsillar crypts, and a vaccine prepared and used. In the meantime the tonsils were treated. Following the vaccine, improvement began promptly and resulted in complete relief except for a slight but painless ankylosis in one wrist.

In connection with the use of vaccines I may state that in no instance was there the slightest evidence of any harmful results following their administration. Excessive doses were avoided and the interval was usually from five to seven days.

The more important points that I would like to bring out in this paper may be summarized as follows:

In this group of cases the fact that in the majority the tonsils are found diseased, the fact that an acute tonsillitis often ushers in an attack and the fact that the removal of tonsils in some cases brings on an acute exacerbation, all point to the tonsil as the common atrium of infection. Other atria exist, of course, but are relatively rare.

Extirpation of the diseased tonsil or focus leads commonly to marked improvement or to complete relief. This points to the tonsil as a focus from which infectious material is being constantly disseminated.

In the diseased tonsils a hemolytic streptococcus is found in nearly all cases, often in pure culture.

This streptococcus invariably produces arthritis in animals. The arthritis may become chronic leading to marked deformities, exostoses, atrophies and hyperplasias of joint structures in animals.

After injection of moderate doses the dead autogenous streptococci may cause acute reactions manifested by swelling, redness and tenderness of the involved joints. This fact points to the streptococcus as the cause of the arthritis. The value of autogenous vaccines in the treatment of many of these cases seems unquestionable, which is also an argument in favor of this streptococcus being the causative agent.

The fact that streptococci from other sources, for example, erysipelas, tend to localize in joints and produce similar lesions when injected into animals should not be used as an argument against the streptococci found in diseased tonsils or other foci being the causative agent in these cases. It is rather an argument for it. Susceptibility of the tissues of the host may in these cases be far more important than specificity of the infecting streptococcus.

The streptococci from these arthritic cases have not been clearly differentiated from streptococci from other sources by the various methods we are able to apply. On the whole, they are probably not so virulent as ordinary pyogenic streptococci.

The group of cases discussed in this paper can be fairly definitely separated both clinically and etiologically from the more miscellaneous group of arthritis deformans on the one hand, and acute rheumatic fever on the other. It would seem appropriate to refer to them as chronic streptococcus arthritis.

1536 East Sixty-Sixth Place.

Why Register Deaths?—It seems to me that there is almost nothing more important in the entire field of statistics than vital statistics, because of their direct bearing on the health and consequent welfare, of the people.—E. Dana Durand, Director of the Census, Washington, D. C.

A BIOLOGIC CLASSIFICATION OF PNEUMOCOCCI BY MEANS OF IMMUNITY REACTIONS *

A. R. DOCHEZ, M.D.
AND
L. J. GILLESPIE, Ph.D.
NEW YORK

The early work of Koch on etiology led him to formulate certain laws which he demanded should be fulfilled before the relationship of any micro-organism to disease could be regarded as satisfactorily established. Subsequent students have sought to fulfil the requirements of Koch, and the result has been that with the elucidation of each well-recognized infection, a single bacteriologic unit has become accepted as the causative agent. Bacteria, however, are not strictly limited in the pathologic process which they induce, and the lesion caused by a single variety may vary somewhat with its location in the animal body. The pathologic and clinical study of disease is, however, so extensive to-day that the various types of activity of the same bacterial race have been thoroughly described and correlated, so that the nature of the infectious agent can in most instances be assumed from the character of the pathologic process.

From the demonstration by Pasteur of the causal relationship of bacteria to disease, and the evidence of Koch that most infections are caused by bacteriologic units, has come the hope that at some time bacterial diseases may be controlled by specific methods. The increasing study of bacteriology and the practical application of bacteriologic immunity to human disease have made it evident that, in addition to the grosser classification of which bacteria are susceptible, certain finer characteristics exist which serve to differentiate still further members of the same bacterial species. In some instances, certain growth phenomena, such as cultural or fermentative reactions, are sufficient for differentiation; others require the extraordinarily specific methods that have developed from the study of immunity. Although, from the point of view of etiology, the drawing of such fine lines of division may be relatively of minor significance, from that of specific therapy these differences are of primary importance. How numerous and important are the varieties of the main bacterial races is not very well known at present. Most investigators recognize the probability of such a condition, and in the specific bacterial and serum therapy of the day, an attempt is made to cover all possibilities by the use of polyvalent vaccines and immune serums. Such serums and vaccines are, however, prepared without much forethought; heterogeneous collections of organisms are used, and difference in origin is the only standard of differentiation of the various strains employed. In such a method, many individuals may be superfluous, and, on the other hand, some important members of the species may be lacking. In this paper we shall report the results of a biologic classification of the pneumococcus, using in the main certain immune reactions for purposes of differentiation.

For the past three years, we have been engaged in a study of lobar pneumonia at the Hospital of the Rockefeller Institute. The problem in the beginning was approached with a view of obtaining, if possible, a specific therapy. The work of Neufeld[1] and his associates has demonstrated the existence of certain varieties of pneumococcus which, in regard to certain of their immunologic reactions, are fundamentally different. In recognition of the importance of this fact, a study of all pneumococci obtained from human cases has been made. Immune reactions have been chosen for purposes of differentiation because of their peculiar specificity and important practical bearing, and because of the inconstancy of morphologic and cultural differences of strains of pneumococcus. A primary classification has been obtained by means of protection experiments. All the strains of pneumococcus, as soon after isolation as sufficient virulence was attained, have been tested for their susceptibility to the action of serums prepared by immunization of animals to single varieties. White mice were used as experimental animals, and the various mixtures of serum and culture were injected simultaneously into the peritoneal cavity. The results were seldom doubtful. If the organism tested belonged to the same group as that from which the serum had been derived, as great a degree of protection was usually afforded as that manifested against the homologous organism. On the other hand, when a strain belonged to a different group, little or no protection was evident, the tested animals dying for the most part within the same time as the controls. The results obtained from testing different strains in the manner described are shown in Table 1.

---

TABLE 1.—CLASSIFICATION BY PROTECTION

	No.	Per Cent.
Group 1	28	45
Group 2	12	20
Group 3 (mucosus)	9	14
Group 4 (heterogeneous)	13	22
Total typical	49	78
Total heterogeneous	13	22
Total	62	

In this table are enumerated in detail the results obtained from testing the protective power of two different immune serums derived from typical organisms. Preliminary work had previously shown that the two strains of pneumococcus chosen for immunization were probably the ones most frequently associated with lobar pneumonia. In the main the differentiation obtained by protection is sufficiently evident to permit a satisfactory classification. In all, sixty-two different strains have been tested against the two types of immune serums. Of the sixty-two strains, forty, or 64.5 per cent., were susceptible to the action of one or the other type of immune serums. On the other hand, twenty-two strains were either completely unaffected by the immune serum or so little influenced as to render inclusion in either of the typical groups unjustifiable. Of the organisms which could be classified by the protection reaction, twenty-eight, or 45 per cent., of the whole number of strains studied responded to the protection of serum Type 1, and shall be called Group 1. The Type 2 serum exhibited protection against twelve strains, 20 per cent. of the whole number studied. These organisms are classed as Group 2. Of the twenty-two strains not materially influenced by the protective action of the serum, nine were easily differentiated by their distinguishing cultural and pathogenic qualities into a group which we have called Group 3, exhibiting the characters of the so-called *Streptococcus* or *Pneumococcus Mucosus.* These organisms are highly pathogenic for white mice and are completely insusceptible to the action of either of the immune serums in our possession. The remaining thirteen strains must be considered as forming a heterogeneous group, designated as Group 4. These organisms do not possess cultural characters that evidently distinguish them from either of the typical groups, and, although one or another of the serums studied may show slightly increased protection, this is so small when compared with the known protective value of the serum that it does not justify inclusion in the typical groups. These differences are further emphasized later in the discussion of the results of agglutination experiments. The results of the work on protection show the existence of four general groups of organisms as the causative agents of lobar pneumonia. Groups 1 and 2 are made up of organisms that are identical from the point of view of protection with other members of their respective groups. Group 3, *Pneumococcus mucosus,* is formed of organisms having distinctive growth characters. Whether or not further classification of this group is possible by means of immunity reactions has not yet been determined because of the difficulty of obtaining satisfactory immune serums against these organisms. Group 4 has no completely distinctive morphologic or cultural characters, and, as is shown later, consists of a heterogeneous collection of isolated individuals.

AGGLUTINATION

A historical discussion of the studies of agglutination of pneumococcus does not seem necessary in this paper. It is sufficient to state that the pneumococcus is agglutinable in specific immune serums, and that evidence in regard to the demonstration of the existence of different varieties by this reaction is contradictory. Pneumococcus does not always agglutinate readily in high dilutions of immune serums. Fortunately, however, it has the property of remaining suspended or growing diffusely in practically pure normal or heterologous serums, so that serum of considerable strength can be used to bring out specific differences. In the following study, serum and twenty-four-hour broth-cultures of the organism were mixed together in equal quantities. The reactions were read by the macroscopic method after one or two hours at 37 C. (98.6 F.), and again after twenty-four hours at either 37 C. or room temperature. Agglutination usually begins to be visible in from fifteen minutes to half an hour, and appears first as a fine granulation of the suspension; the clumps finally sink to the bottom of the tube and in the end usually form a firm, scale-like mass in the bottom of the tube which cannot be broken up, even by vigorous shaking. If the mixtures are allowed to stand for twenty-four hours at 37 C., a precipitation of serum and organisms sometimes occurs in the control tubes which, however, after a little experience is easily distinguishable from a true agglutination. In control tubes, even when such a precipitation occurs, the majority of the cocci remain freely suspended, whereas when specific agglutination develops, the supernatant fluid always becomes perfectly clear. The organisms studied were tested against the same two types of serums used for the protection experiments, and the results obtained are shown in the Table 2.

Study of the agglutination reactions of these strains of pneumococci shows that specific differences can be brought out by this method between individual members of a collection of organisms. The strains again fall into definite related groups, and the percentage of distribution is about the same as that obtained in protection experiments. In every instance in which an organism could be definitely placed by protection in one of the groups described, the agglutination reaction has corre sponded with this classification. Two strains, 56 and 86, showed doubtful protection with both types of serums, but on agglutination reacted specifically with serum Type 1.

TABLE 2.—CLASSIFICATION BY AGGLUTINATION

	No.	Per Cent.
Group 1	22	41
Group 2	11	20
Group 3 (mucosus)	9	17
Group 4 (heterogeneous)	12	22
Total typical	42	77
Total heterogeneous	12	23
Total	54	

By the methods of protection and agglutination, it has been possible to classify the pneumococci associated with lobar pneumonia in man into four groups. Groups 1 and 2 consist of members closely related immunologically to other members of their respective groups. Group 3 is formed of *Pneumococcus* or *Streptococcus mucosus*. Of nine members of this group studied, eight possessed the common characters of pneumococcus in addition to the quality of forming mucus, and one those of streptococcus. The latter organism was insoluble in bile, failed to ferment inulin, hemolyzed blood mediums, and exhibited other characteristics of *Streptococcus longus*. It formed, however, abundant mucous exudate in animals, grew in large mucoid colonies and showed well-developed capsules. A study is now in progress to determine whether or not immunologic differences exist between individual members of the mucous group. The fourth group consists of heterogeneous members, and a further study of this group appears later. All the strains of pneumococcus examined were studied by the usual cultural methods. Although average cultural and morphologic differences exist between the different groups, these are variable and are not reliable for purposes of identification, except those of *Pneumococcus mucosus*. All the strains studied, except the *Streptococcus mucosus* mentioned before, were either bile-soluble on isolation or have become so on animal passage. Fermentation of inulin is not more characteristic of one group than another. Capsules are somewhat easier to demonstrate among members of Group 1 and *mucosus* than in Group 2 and the heterogeneous group. The average morphology of the various groups shows some differences. In Group 1, individual cocci are medium-sized, slender and show a slight tendency to rounded ends. Individuals of Group 2 are larger, fairly broad and almost invariably show perfect lancet-shaped forms. The morphology of *Pneumococcus mucosus* is quite characteristic, showing voluminous capsules containing medium-sized, closely approximated cocci with definitely rounded ends. In general, members of the heterogeneous group tend to exhibit pairs of rounded individuals, but may resemble completely either Group 1 or Group 2. The virulence for mice of strains of the typical Groups 1 to 3 is usually higher and more constant than that of the heterogeneous Group 4. A continuous study of a number of members of the different groups may thus bring out certain more or less characteristic differences. These, however, are not constant, and cannot be depended on for purposes of classification.

The frequency with which the different types of pneumococcus appear as the cause of lobar pneumonia is of considerable interest. Altogether it has been possible to obtain a biologic classification of the pneumococci from seventy-four cases of typical lobar pneumonia. In thirty-five instances, 47 per cent., the organisms belonged to Group 1; in thirteen instances, 18 per cent., to Group 2; in ten instances, 13 per cent., to Group 3 (*mucosus*) and in sixteen instances, 22 per cent., to Group 4 (heterogeneous). Almost one-half the cases of pneumonia which we have seen are due to pneumococci belonging to Group 1. Members of the other groups occur less frequently. In 78 per cent. of the cases examined, the organisms obtained have possessed distinguishing characteristics which permit a definite biologic grouping. The remainder do not have distinctive common immunologic or growth characters and must be classed as heterogeneous. Immune serums have been prepared with organisms from Groups 1 and 2, and apparently all members of these two groups are susceptible to the protective and agglutinative action of these serums. The immunity reactions of Group 3 (*mucosus*) have not as yet been completed.

Group 4 has been called heterogeneous. The reason for this classification is shown in the following study: Animals were immunized to various members of this group and the immune reactions which had been found to be common to members of Groups 1 and 2 were studied. So far, it has not been possible to protect animals against any of the heterogeneous strains, when serum derived from another strain has been used. The immune serums obtained protected against only the homologous organism. An example of the method employed is shown in Table 3. The immune serum was obtained by immunization of an animal to Pneumococcus 71. The cultures used for infection were twenty-four-hour broth-cultures, freshly obtained from passage through animals. Culture and serum were injected simultaneously into the peritoneal cavity of white mice.

Certain other strains belonging to the heterogeneous group have been tested in the same manner, and in no instance has any cross-protection been observed. From Table 3 it is seen that not only does Serum 71 fail to afford any protection against heterologous strains, but in some instances even increases the fatality of the smaller doses of culture. The serum, however, possessed a high protective power against the homologous organism. The condition of affairs is, therefore, quite different in this group from that observed in Groups 1 and 2. In the latter a serum derived from one member of the group seems to protect animals against infection with all other members of the group, whereas in the former, no instance of cross-protection has been observed.

In addition to the protection reactions, cross-agglutination among members of this group has been carefully studied. The technic employed was the same as that previously described. The results are shown in Table 4.

In this table the results obtained from testing fourteen different strains against serums derived from eleven of the strains are presented. The agglutination reaction has again confirmed the results of protection experiments. In only one instance was cross-agglutination observed, Pneumococcus 55 by the polyvalent serum obtained from Pneumococci 34, 38 and 71. In two other instances, Pneumococci 37 and 52, agglutination occurred in heterologous serum, but the reaction took place much more slowly than that of the homologous organisms. The study of cross-protection and agglutination among members of the heterogeneous Group 4 indicates that this group comprises a number of distinct varieties of pneumococcus which cannot be related to one another by immunologic reactions. Culturally they are true pneumococci and manifest all the common characters of pneumococcus.

The study of certain biologic reactions of a large number of strains of pneumococci isolated from cases of pneumonia in man has developed some interesting facts. The organisms studied fall into two general groups. One of these, containing a large majority of all strains investigated, consists of three apparently fixed races, and the other of a smaller number of strains, each of which seems to form a distinct variety. The individual members of two of the fixed races (Groups 1 and 2) can be distinguished certainly from one another only by means of highly specific immune reactions. Single strains, however, belonging to either of these two groups have immune reactions in common with all other members of the particular group to which they belong. The other apparently fixed race consists of the organisms designated as *Pneumococcus mucosus*. Although the latter classification has been based on cultural reactions and does not exclude the existence of different varieties, from the point of view of immunity, incomplete immunologic studies indicate that most of these organisms can also be further related by means of immunity reactions. In striking contrast to these three groups is the fourth or heterogeneous group, which seems to consist entirely of isolated individuals. The significance of such a situation is difficult to interpret. Whether this mixture is being progressively differentiated into groups with common characters, or whether each member is a descendant of one of the fixed groups that has undergone a fundamental change by being forced to adapt itself to some special environment, cannot be determined from the evidence at hand. It is not impossible that the fixed races are more highly parasitic and are never very far removed from a condition of pure parasitism, whereas the heterogeneous strains may be representatives of the type of pneumococcus found in the normal mouth and consequently more likely to have undergone environmental changes.

The specificity of the immunity reactions has been very striking and, from the practical point of view of specific therapy, is of great importance. A large amount of work has been devoted to study of the agglutination reactions of pneumococcus. Kindborg[2] has found that satisfactory agglutination occurs practically only when homologous serums are used. On the other hand, Hiss[3] has obtained a wide degree of cross-agglutination. Such contradictory results may largely depend on the investigator's luck in securing suitable organisms. If the collection should consist of a majority of members of one of the fixed groups, cross-agglutination would be the rule, whereas if the heterogeneous strains should predominate, a high degree of individual specificity would be observed. The fact that cross-protection does not occur except among members of individual groups of the fixed races has an important practical bearing. If polyvalent serums are to be used in the therapy of lobar pneumonia, such serums must be derived from representative members of the typical groups, if the therapeutic application is to be successful. On the other hand, if one uses univalent serums, representing each of the fixed races, a diagnosis of the type of organism concerned in individual instances of the disease must be made. The latter method is quite practicable and has been successfully employed at the Hospital of the Rockefeller Institute during the past year. Whether or not the results obtained from this study of pneumococci can be profitably applied to other pathogenic bacteria cannot be definitely asserted. It is not, however, illogical to assume that such a classification of other infectious organisms could be made. If this is true, in order that specific bacterial and serum therapy may be intelligently applied, such a study becomes imperative.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. CAPPS, DAVIS, DOCHEZ AND GILLESPIE

Dr. Frank Billings, Chicago: In chronic joint infection one must remember the blood-supply of the joints. It is distinct for the periarticular structures, for the synovial membrane

---

2. Kindborg: Diss. (Halle), Leipsic, 1905. Ref. Centralbl. f. Bakt., 1906, Part 1, xxxviii, 172.
3. Hiss: Jour. Exper. Med., 1905, vii, 547.

and for the medulla of the bones which enter into the joint. Blood infection may take place only through these three channels. That explains why infection may at one time be periarticular or synovial, and at another osteoarthritic, or why all three types of infection may be present in a joint at the same time. I believe that many of the chronic joint diseases are infectious: even in some of the senile joint troubles infection may be a coincidence. The word senile must include the atrophic degenerations of the joints which at times occur in relatively young individuals. The morbid anatomy of chronic joint infections may be so nearly alike for various bacteria that the pathologist cannot differentiate them. The clinician may, however, group these different forms of infectious joint trouble because of rather characteristic clinical phenomena. For instance, a streptococcus infection may not only produce a periarthritis or synovitis or osteo-arthritis or changes in all three structures of a joint, but may also produce a chronic myositis. In probably every chronic streptococcus joint infection there is a myositis present in some part of the patient's body. Usually this is selective and involves the biceps humeri, the masseter, the erector spinae, the hamstring, the quadriceps femoris and the anterior tibial group of muscles. I do not mean that all of these different groups of muscles are involved in any one patient, but some of them may be. In addition, the patient who has been ill for a considerable period will show alteration in the general nutrition and metabolism, as evinced by an overgrowth of hair on the extremities, a change in the nutrition of the nails and often an evidence of atrophy of the skin itself. In all probability these malnutritional metabolic changes are the result of the long illness, but may be secondarily due to the infective agent. The streptococcus group can therefore be set aside clinically because of the attendant chronic myositis. The gonococcus chronic joint infections may have a morbid anatomy so like that of the streptococcus that one cannot differentiate, but clinically I have never seen a myositis in gonorrheal arthritis; there is frequently present, however, a tenosynovitis, and tenosynovitis I have never seen in streptococcus chronic arthritis. In the treatment one must first locate and remove the chronic focus of infection. This must be done thoroughly. Following this the patient must have a long period of rest, and this time of rest must, of course, be individual. The patient must have good, wholesome food to improve the general nutrition. To improve the immunity of the patient, in addition to the measures already described, one may use autogenous vaccination, which is of secondary importance as compared with the rest treatment and attention to the general nutrition of the patient. If autogenous vaccination is used it is possible that some benefit may result, if a bacteriologic diagnosis has been made in advance, from the use of commercial stock vaccines chosen on the basis of the bacterial diagnosis. Stock vaccine chosen on any other basis is a haphazard method of treatment.

On these principles I have managed patients with chronic arthritis with unusually good results, amounting to recovery in cases in which the joint changes have not gone on to a destructive stage and in severe types to improvement of the patient by bringing to a stop the progress of the disease.

Dr. G. L. Richards, Fall River, Mass.: In the last few years many patients have been referred to us on account of rheumatism. I should like to know whether Dr. Davis advises the removal of the tonsil whenever the diagnosis of rheumatism is made, or would he depend on the determination of streptococci in the tonsil? I refer especially to the small tonsil in which, if you draw the anterior pillar back, you may find a little tonsillar secretion or partially coagulated secretion or pus. Should we have a culture made from the surface of that tonsil before we take up the question of operation?

Dr. Davis spoke of cases in which the tonsillotome was not used because of the blood-pressure. What is the limit of blood-pressure which would contra-indicate operation?

After the operation of tonsillectomy there is a certain refilling of the spaces between the anterior and posterior pillars, and the laryngeal follicles at the base of the tongue may enlarge a little. Is there not some tendency of the infection to occur again, or is the danger from rheumatism over after the removal of the tonsil?

Although tonsil operating is being done rather indiscriminately throughout the United States at present, operations on the tonsil require just as much care as any other type of operation and should be attempted only by those who possess the proper qualifications.

Dr. Henry Albert, Iowa City, Iowa: I should like to ask Dr. Capps in what proportion of the cases of epidemic sore throat of milk origin there was tonsillitis and in what proportion pharyngitis. I presume it is almost always a follicular tonsillitis. During the past year I performed some experiments which, I believe, might be applicable in the treatment of the cases of tonsillitis accompanied by rheumatism. With the idea of treating diphtheria carriers I aimed not only at disinfecting the crypts of the tonsils, but also at producing a reaction. This was done by the use of silver nitrate. I used solutions of different strength (from 5 to 40 per cent.) applied to the tonsillar crypts, five minutes, fifteen minutes, one day, two days and seven days before the removal of the tonsils. I found that, if a solution stronger than 10 per cent. was well applied to the crypts, the entire epithelial layer would be destroyed. In almost any strength there was considerable inflammatory reaction. The experiments were not continued long enough in any case to show whether or not there was any occlusion of the crypts. The immediate effect of the silver nitrate is a destruction of the epithelial lining of the crypts. I hoped that, before the cells could regenerate, there would be sufficient proliferation of the fibroblasts to lead to occlusion of the crypts of the tonsils. At any rate, so far as the diphtheria-carrier condition was concerned, this treatment had good effect, and I do not see any reason why that would not be a good procedure when the removal of the tonsil is objected to, especially in view of the fact that the removal of those tissues sometimes causes an exacerbation of the joint lesions.

Dr. Norman Bridge, Los Angeles: I should like to say a word from the point of view of the practicing physician. These investigations are among the most valuable that have been made. They are interesting because physicians cannot entirely agree on some of the questions, for instance, the character of the micro-organism. That makes for progress and is unavoidable in the development of the science of bacteriology. The lesson to the practicing physician, however, is one of the most momentous of all. It seems to me that we are coming to the point of believing that a large percentage of the cases of acute rheumatism originate in the tonsil, whatever the character of the microorganism may be. There is a considerable proportion of young persons, more young than old, who acquire acute rheumatism and endocarditis with leaky valves, and live on through life more or less crippled as a consequence. It seems to have been proved that removing the tonsils does no harm. Removing them, moreover, completely abolishes one source of infection. It seems as though we were coming to the point of finding it a duty to advise the removal of the tonsils as a regular and standard measure for the protection of the young. I do not know that I would advise that to-day, but this will be the practice in the future, judging by the proofs that are being accumulated through the labors of students of biology. I am positive that the tonsils should not be removed by the man who is simply capable of using a tonsillotome, and they should never be removed by the old-fashioned tonsillotome; they should be enucleated completely by the most modern method by those familiar with this operation. I am anxious to hear whether or not there is any definite scientific objection to advising parents that it would protect the lives of their children, at least protect against possible rheumatism and chronic arthritis, if the tonsils were removed.

Dr. Louis F. Jermain, Milwaukee, Wis.: Considerable stress has been laid on the importance of the tonsil as a portal of entry for invading micro-organisms to joint structures. Attention has also been directed to sinus disease and other possible foci. In this connection, we must not forget suppurative processes in the mouth and especially of the teeth and gums. I believe that the primary focus is often in the teeth and gums, and the infection spreads from there to the tonsils or may invade the body directly. In my own case I am certain that a bacterial invasion occurred in this manner, namely, primarily in the gums, thence to the tonsils and subsequently to joints. What I wish to emphasize is, that we should not be content with a removal of the tonsils, but should endeavor to eliminate all possible foci of invasion.

Dr. J. A. Capps, Chicago: In reply to Dr. Albert's question I would say that in most of the cases in all these epidemics a redness of the throat is described which is diffuse, spreading over both the pharynx and the tonsils, so that one can say there is both pharyngitis and tonsillitis. In some cases there is an exudate thick enough and extensive enough to resemble a diphtheritic membrane.

Dr. D. J. Davis, Chicago: In answer to the question of Dr. Richards concerning the extirpation of the tonsils, I would say that this is not always an easy matter to decide. In chronic arthritis the tonsils are at fault in most cases. Our attention is therefore directed first to a careful examination of these organs. Other foci may also be present. For example, alveolar abscesses are not infrequent. They frequently occur with infected tonsils. Either one or possibly both may be at fault; or one may depend on the other. There may be still other foci. This all means that we must subject the entire body to a most careful physical examination. If the tonsils are diseased they should be treated. If the teeth are diseased they should be treated. I think that one can often, but not always, detect these tonsillar infections from the appearance of the tonsils. But sometimes the tonsils are smaller than normal. At times also by a careful examination one can find little pockets of pus in tonsils that look quite normal on the surface.

There will perhaps be cases now and then in which no focus can be found. Under these conditions I think one is justified in enucleating the tonsils with the hope that this operation may do good. The bacteriologic examination should be correlated with the other findings. It ought to be quite unnecessary to say that in every instance complete enucleation should be carried out. In four of the cases referred to the tonsils had been removed previously; that is, the top of the tonsil had been sliced off. This operation did absolutely no good. There were recurrences and I am inclined to believe that this operation is actually dangerous, because it causes the fibrous tissue to form about the openings of the crypts preventing proper drainage.

The case of high blood-pressure that I mentioned occurred in a man, about 60 years old, suffering with chronic arthritis. The blood-pressure ranged from 190 to 210 and as he had had some experience with hemorrhage, it was thought unwise to operate on the tonsil. The crypts were opened and pus was obtained. It was clear that they were infected and vaccination and treatment of the tonsil resulted in a striking recovery. I have not made any bacteriologic examination of the lymphoid tissue of the pharynx.

THE TEACHING OF LABORATORY PHYSIOLOGY

A. D. BUSH, M.D.
Instructor in Physiology, Medical Department, University of Vermont
BURLINGTON, VT.

At a time when there is growing complaint about the overcrowding of the medical curriculum, resentment among undergraduates at the waste of time in conducting apparently fruitless experiments, and caustic criticism among graduates aimed at the teaching of isolated facts of undemonstrable utility, it may not be amiss to examine some of the conditions toward which adverse comment is directed. Possibly the irritation felt has a justification; possibly the curriculum might be lightened and improved by clearing away the relatively unessential and placing more emphasis on data of unquestioned adaptability. That such a clarifying investigation might be profitably conducted in nearly every branch of medical teaching seems to be generally believed by the practicing profession. The present discussion, however, must be limited in subject-matter principally to laboratory physiology.

As a brief preliminary, it should be accepted as axiomatic that the matriculant in medicine is thereby a self-limited specialist. He has chosen to concentrate his energies in acquiring the difficult art of preventing as well as curing the varied ills to which human flesh seems heir. He seeks specific knowledge, not desultory information; purposive data, not cursory generalities. To assist him in realizing his laudable ambition, great stress should be laid on such facts as have well-defined utilizable value in the practice of medicine and surgery. Such facts as have but a remote relationship to the practice of medicine may well have their consideration deferred until the more important subjects have been disposed of. So it is, when the medical student enters the laboratory of physiology, he comes seeking experimental demonstrations concerning the functioning of all the structures of the human body, the architecture of which he has been studying in the laboratory of anatomy. He does not seek, as he does not need at this time, information concerning the reactions of *Rotifera, Coelenterata* or *Batrachia*. General biology and zoology belong to the academic side of the university and should there be considered, if at all, in a course preliminary to the medical. Likewise, comparative physiology—an intensely interesting subject—should not be allowed to usurp time vitally needed for consideration of the far more important subject of human physiology. That time spent on experiments in general biology constitutes a usurpation is shown by the fact that no medical school, so far as can be learned, has sufficient time in its course in laboratory physiology to do even scant justice to some divisions of the subject; notably, physiology of the brain. Yet, I submit, it is infinitely more important that a student learn those fundamental tests of normality whereby he may be enabled to save a handicapped child from condemnation to relative idiocy than it is that he should be conversant with the graphic record of heart-block in *Rana esculenta*.

A depressing amount of time is spent in worrying about the elasticity, contractility and spasticity of the frog's gastrocnemius, in entire forgetfulness of the fact that many of the so-called classic experiments are now of historical interest only. It is not to be denied that many of the routine experiments were of much value as original investigations; but such value fails to reappear when the experiment is repeated in the laboratory of human physiology, inasmuch as its original purpose is neglected, and, moreover, it is not demanded by present circumstances. The function of the department of physiology in a medical school is to give students a vivid acquaintance with the varied activities of the normal human body; it is not its function to fritter away the time of embryonic expert clinicians by making haphazard, elementary drives at abstruse research. If there be discovered, occasionally, a student possessing the qualifications peculiar for research, he may easily be singled out and given such problems as his time and ability permit. To the average student, however, it is an injustice to require him to use his time performing experiments of inconsiderable value. Moreover, to quote Thorndike.[1]

---

[1] Thorndike: Education, p. 178

experiments conducted on animals. For all the frog muscle-nerve experiments having any possible medical significance, it is perfectly feasible to substitute related experiments on living human subjects. Who will deny that, for medical students, such substitution would greatly augment the value of the experiments? The data obtainable by animal experimentation in the research laboratory can be far more scientifically imparted by a few moments' intelligent discussion, or demonstration, than by several hours of crude attempts by amateurs at the same experiment. It is, moreover, as uneconomical as it is unscientific to spend two hours in learning by instrumental manipulation what could be more thoroughly comprehended by five minutes of concentrated thinking. Circulation experiments by vivisection provoke some curiosity and wonder, when similar demonstrations with mechanical models stimulate imagination, reason and judgment. There seems no limit to the illustrative devices possible to scientific ingenuity, automatons imitative of practically every bodily movement and function being readily contrivable; and such models, because of their simplicity and definiteness, are much more richly illustrative than anything a student can ordinarily obtain from the anesthetized cat, dog or guinea-pig.

A few searching questions asked of the average practitioner quickly show that there is considerable need for experimental work so arranged as to illuminate the actions of muscle-groups as well as of individual muscles; and this work might well be preceded by a carefully selected series of experiments dealing with the physiology and mechanics of bones and joints. For experiments in circulation and respiration no animal experiments (capillary circulation excepted) can compare in value with the data obtainable from examinations of fellow-students, and from manipulating mechanical models. Experiments in digestion and absorption have been largely transferred to a separate department of chemistry. The special senses could well receive much more attention than the customary allotment, while the brain, with its activities as manifested in emotional and intellectual states, should be given extensive attention in laboratory investigation. No division in physiology is more important; no section is more neglected. Even "standard" text-books on physiology devote their consideration of the central nervous system to a discussion of anatomy and somatic reflexes. And, as Loeb well says:[7]

> We can no more expect to unravel the mechanism of associative memory by . . . morphologic methods than we can expect to unravel the dynamics of electrical phenomena by . . . counting and locating the telephone connections in a big city.

Very little brain physiology as expressed in mental states is discoverable in any text-book. Yet such states exert a tremendous influence on all with which the physician has to deal. Therefore both their conditions and revelations need and deserve careful, serious consideration. True, such a course constitutes physiologic psychology; but who needs such a course more than the physician? Certainly society needs to have every physician trained in such a course.

Let us clear away our pedagogic cobwebs. Let us throw out from our medical curriculum everything not demonstrably applicable and, in its place, let us give a course of applied science throughout. So may our burdened curriculum be lightened, our students held with intense interest, our graduates strengthened to grapple more adequately with their problems, and society cheered and comforted.

SUMMARY

I can do no better, in closing, than to quote the following pregnant words from O'Shea:

> "In every machine there are economical as well as wasteful methods of operation, and the same must be true in principle of the brain. A given amount of force can accomplish more in promoting activities in well-organized than in poorly-organized areas."[8] Hence "an individual should be required to perform during his learning-period those activities which he will be called on to perform most often in maturity. He must be practiced in doing as an apprentice what he will have to do as an artisan."[9]

A STUDY OF THE SPINAL FLUID IN ONE HUNDRED CASES OF SYPHILIS

INCLUDING INVESTIGATIONS FOR ARSENIC AFTER INTRAVENOUS ADMINISTRATION OF NEOSALVARSAN [*]

M. F. ENGMAN, M.D., RUDOLPH BUHMAN, M.D., F. D. GORHAM, M.D., and R. H. DAVIS, M.D.
ST. LOUIS

Examination of the spinal fluid has in recent years become of great value in the study of syphilis of the nervous system, particularly in the so-called parasyphilitic conditions, tabes and paresis, which we now know, through the investigations of Noguchi and others, to be not parasyphilitic but due to the invasion of the cerebrospinal system by the *Spirochaeta pallida* itself.

We undertook the investigation of the cerebrospinal fluid on account of the definite findings that can be demonstrated in it to indicate an invasion of the cerebrospinal system by the *Spirochaeta pallida*, the purpose being to determine what percentage of patients with syphilis applying for treatment at a general dermatologic clinic would show evidence of spinal invasion.

The large percentage of early syphilis reported in literature as giving evidence of meningeal disturbance encouraged us. All of the cases of syphilis, therefore, in the outpatient department of the Washington University Hospital and the Barnard Free Skin and Cancer Hospital, if the patient would submit to spinal puncture, were studied.

All of the cases in the investigation were examined in the following manner: Blood and spinal fluid were obtained simultaneously and a Wassermann reaction made on the two fluids, two separate antigens being used with increasing amounts of spinal fluid, beginning with 0.2 c.c. and increasing to 0.5 c.c. The cells in the spinal fluid were counted from undiluted fluid in the ordinary blood-counting chamber. The globulin reaction was determined by the Noguchi method. Fehling's reduction test was also performed on each fluid, as normal spinal fluid reduces Fehling's solution, owing supposedly to the presence of pyroincrease in the size of the heart. A study of the heart-weights in the group showed in the 20 cases without endocarditis only 10 with a weight exceeding 300 gm. Of these 10 the heart-weight of five exceeded 350 gm.

[*] Read in the Section on Dermatology of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

[*] Because of lack of space, this article is abbreviated in THE JOURNAL. The complete article appears in the Transactions of the Section and in the authors' reprints.

In these 5 cases with this degree of cardiac enlargement there were 3 cases with arteriosclerosis, 1 case of exophthalmic goiter, and 1 case of subacute glomerulonephritis. Cardiac enlargement is present frequently in each of the foregoing conditions, so that the heart hypertrophy may have been caused in part in these 5 cases by the associated disease as well as by the adhesions.

Of the 6 cases in Group 1 with endocarditis, 5 had a degree of heart enlargement exceeding 350 gm.; 1, 732; 2, 528; 3, 510; 4, 403; 5, 370. The average weight of the hearts in this group was 352 gm. Cardiac enlargement was not marked in those cases in which tuberculosis may have been a factor in the production of the adherent pericarditis in the absence of endocarditis or nephritis. The average weight of the heart was but 340 gm.

From the study of the effects of adhesions it would seem from these cases in Group 1 that no marked increase in the size of the heart need follow slight adhesions, bands or even pericardial obliteration, in the absence of some other well-recognized cause for heart enlargement, as endocarditis, nephritis or arteriosclerosis.

In one case, in a woman aged 28, in which both pleural cavities were obliterated as well as the pericardial cavity, with binding down of the sternum, the heart-weight was but 377 gm.

A study of the clinical records failed to show any heart murmurs in these cases in Group 1 which were not to be explained by the associated endocarditis, arteriosclerosis and relative mitral regurgitation present.

The unimportant Group 1 may be dismissed from further study.

Two striking things in Group 2 are noted: (1) the presence of one or more rheumatic attacks in the history in 22 of the 36 cases; (2) the presence of endocarditis in 27 of the 36 cases.

The diagnosis of rheumatism is so ill-defined that great care in attributing rheumatism as a factor in the production of adherent pericarditis was taken. Careful examination of the previous record showed that in 13 of the 22 cases there was no doubt of the previous rheumatic infection; in 5, the diagnosis of a previous rheumatic attack was probable; in 4 it was possible.

In the etiology of these cases of adherent pericarditis in Group 2 there was no other infective disease so prominent in the previous history as rheumatism. In 8 cases tuberculosis of a bronchial or mesenteric lymph-node was found post mortem.

The 27 cases of endocarditis in Group 2 were as follows:

Acute endocarditis alone, 6:	
Aortic and mitral	4
Aortic alone	1
Mitral alone	1
	6
Chronic endocarditis alone, 12:	
Aortic and mitral	5
Aortic alone	1
Mitral alone	3
Aortic, mitral and tricuspid	2
Aortic, mitral, tricuspid and pulmonary	1
	12
Acute and chronic, 9	
Aortic and mitral	6
Mitral alone	1
Aortic, mitral and tricuspid	2
	9

The influence of the adherent pericardium is difficult to determine in the presence of endocarditis of such extent as in Group 2. The mitral and aortic valves showed endocarditis 15 times, mitral alone 5, aortic alone 2, aortic, mitral and tricuspid 4, and aortic, mitral, tricuspid and pulmonary 1. In the endocardial damage itself, sufficient cause for death existed if we judge from similar cases of endocarditis without adherent pericarditis.

It is of interest that of these patients with positive, probable, or possible rheumatic infection, endocarditis was present in every case except one.

In group 2 the heart-weights are available in 31 of the 36 cases. The weight of the heart was over 300 gm. in 29 of the 31 cases:

Gm.	Cases.	Gm.	Cases.
300-400	6	820	1
400-500	7	1,150	1
500-600	8	1,273	1
600-700	3	1,328	1
700-800	1		

In 7 of the cases the pathologic condition made it necessary to include the pericardium in the heart-weight.

The average weight of the heart in this group was 592 gm.

It is impossible from a study of these cases to state what part the pericardial adhesions may have had in the production of the cardiac hypertrophy. The fact that cardiac hypertrophy was not marked in the cases in Group 1, in some of which the adhesions were equally extensive, would point toward the belief that the cause of the heart hypertrophy is more apt to be associated with the primary rheumatic condition or the associated endocardial lesion.

Attention has been called to the effect of the toxin on the myocardium in cases of acute rheumatic infection, notably by Fisher.[1] He says:

> The view that rheumatism can produce toxic enlargement of the heart is also supported by the fact that in rare instances cardiac hypertrophy and dilatation may be seen in the postmortem room following rheumatism when neither pericardial adhesions nor lesions sufficient to interfere with the function of the heart valves prove to be present. Isolated cases have been reported in which, post mortem, marked changes in the myocardium follow rheumatic infection.

Weil and Gallavardin[2] have recently reported such a case.

Fenton lays more importance on the effect of the rheumatic poison on the heart muscle than on the endocardial or pericardial changes. He says:[3]

> The train of events, which leads up to the clinical picture noted in connection with chronic adherent pericarditis, appears to be that the main pathologic condition associated with this lesion is one of dilatation, the result of the action of the rheumatic poison on the heart muscle and subsequent hypertrophy. Dilatation takes place during the acute or subacute periods of the phase which precedes the chronic adhesion. In a few mild cases it may pass off, but in the great majority it does not, and hypertrophy and external adhesions follow, resulting in a condition of unstable equilibrium in which the constant tendency is to increase dilatation and failure, owing partly to a certain amount of embarrassment to systole, caused by external adhesions, but mainly to a permanent damage to the heart muscle, in a measure resembling those cases of chronic cardiac failure in more advanced life in which there is nothing to account for the symptoms but functional change in the properties of the heart muscle, and which is generally accompanied by progressive decline in its powers.

[2] Weil and Gallavardin: Arch. de méd. des enf., 1900, ii, 193.

[3] Fenton: Adherent Pericardium, Practitioner, lxxxi, 637.

The presence of nephritis in 11 of these cases in Group 2, in 6 of the glomerular type, makes it even more difficult to attempt an interpretation of the part the pericardial adhesions may have played in the heart enlargement.

The effect of adherent pericarditis in the absence of a rheumatic infection in the history, and in the absence of endocarditis may be studied in the 8 remaining cases in this group. The heart-weights are available in 7 of the 8 cases. In 6 of the 7 cases the weights were over 400 gm.; in one, a boy of 10, with adherent pericarditis, following osteomyelitis, the heart-weight was 135 gm. A glance at the chief cause of death in these cases with enlarged heart shows that the adherent pericarditis apparently was of no great importance in the production of the heart enlargement, or in the cause of death.

1. Arteriosclerotic nephritis, cardiac thrombosis.
2. Chronic interstitial nephritis, coronary arteriosclerosis, chronic lead-poisoning.
3. Amyloid nephritis, syphilis, hypertrophy, dilatation of heart.
4. Aneurysm of aorta.
5. Dissection aneurysm with rupture.
6. Arteriosclerosis, cardiac thrombosis.
7. Osteomyelitis, empyema.
8. Chronic interstitial myocarditis with cardiac aneurysm, chronic pleuritis, perihepatitis and perisplenitis.

In Case 8, with pleuritis, perisplenitis and perihepatitis, the condition of the pericardium is stated to be as follows: In the region of the apex over the wall of the left ventricle, near the interventricular septum, there is a broad band of dense, fibrous tissue binding the parietal and visceral pericardium together. The incidence of lead in one, and syphilis probably in three, is of interest in these cases.

Careful analysis of the murmurs recorded in the records in these cases of Group 2 failed to show any murmurs which could not be explained by the associated endocarditis, or by the heart condition, independent of the adherent pericarditis.

The reason why adherent pericarditis is overlooked is apparent from a study of these two groups of cases. In the first place, the direct signs or symptoms suggesting the cardiac condition are so slight that attention is not attracted to adherent pericarditis as a possibility, in the presence of some other prominent, well-defined condition from which the patient is suffering. On the other hand, judged by this group of cases, in which cardiac symptoms were present, and adherent pericarditis might have been considered, in only one case of the 37 was there no other cardiac or renal manifestation which might not explain the cardiac symptoms. With endocarditis present in 27 of the 36 cases in the group in which cardiac symptoms were prominent, and well-defined pathologic changes present to account for the cardiac symptoms in 8 of the 9 remaining cases without endocarditis, there is left but a single case of cardiac death in which, post mortem, no endocarditis and no glomerulonephritis were present.

In this one case, in a girl of 11, with a previous rheumatic history who died from cardiac decompensation, the anatomic diagnosis was chronic adhesive pericarditis, hypertrophy and dilatation of the heart; chronic passive congestion of lung, liver, spleen and kidneys; ascites; hydrothorax; slight edema of lower extremities, and hypoplasia of uterus. The pericardial sac was everywhere adherent to the surface of the heart by firm connective tissues.

A study of the clinical record of this case shows that the heart impulse was palpable with corresponding dulness just beneath the sixth rib, 10 cm. from midsternum, from 3 to 5 cm. outside the nipple line; to right 2 cm. outside the third space. Action regular, rapid; loud, blowing systolic murmur at apex, replacing first sound, transmitted to axilla. Pulmonic second accentuated. Same murmur heard over precordia and back. Pulses equal and synchronous, of small volume and low tension. Liver from the sixth rib to 4 cm. below costal margin, nipple line. Considerable edema of feet and legs. White count 34,000.

Endocarditis, acute or chronic, would be a much more usual diagnosis to make in this case with decompensation, a loud transmitted murmur, with cardiac enlargement and leukocytosis. The apex in the sixth space, in the absence of nephritis, should not have permitted the diagnosis to be mitral regurgitation, unless that regurgitation was a relative mitral regurgitation associated with the left ventricular hypertrophy; or if so considered organic mitral disease, some other cause for the left ventricular hypertrophy should have been sought.

In 33 of the 36 cases in Group 2 the adherent pericarditis may be said to have been of the cardiac type. In three patients there was an associated perihepatitis and perisplenitis. In one, a boy of 7, the abdomen required frequent tappings; in the other two, women of 35 and 65 years, respectively, no ascites could be demonstrated. In one patient ascites was found post mortem.

No attempt has been made in the study of these cases to determine the clinical manifestations of the adhesive pericarditis. Analysis of the cases in Group 2 will be made later with this point in view.

From a study of these 62 cases, in which adherent pericarditis was present at post mortem at the Massachusetts General Hospital, two groups may be made, as in the accompanying tabulation.

GROUPING OF SIXTY-TWO CASES IN WHICH ADHERENT PERICARDITIS WAS PRESENT AT THE POST-MORTEM

	Group 1.	Group 2.
Cases without cardiac symptoms......	26	36
Average age, years....................	47.5	35.4
History of rheumatism	6	22
Endocarditis	6	27
Cardiac enlargement	not marked	marked
Average heart-weight, gm..............	352	592
Pericardial adhesions..................	less extensive	extensive
Pleuropericardial adhesions	rare	common

CONCLUSIONS

1. From a study of these cases, it may be said that adherent pericarditis may be impossible of diagnosis in cases like those of the first group unassociated with cardiac symptoms, cardiac enlargement or murmurs. The diagnosis under such conditions is unimportant, as in this type of the disease it probably contributes but little to the disability of the patient.

2. A second type in young adults, with a previous rheumatic history, with associated endocarditis, is serious. Adhesive pericarditis is overlooked because the coincident endocarditis appears in the foreground. Adhesive pericarditis should always be thought of in a young adult whenever rheumatism followed by endocarditis appears in the history, and especially considered when the cardiac failure is more marked or the cardiac enlargement more extensive than the endocardial damage seems to warrant.

3. More careful records should be made of the presence or absence of cardiac dilatation in cases of acute rheumatism without endocarditis or pericarditis.

377 Beacon Street.

THE INTENSIVE TREATMENT OF SYPHILITIC NERVOUS AFFECTIONS CONTROLLED BY EXAMINATIONS OF THE CEREBROSPINAL FLUID [*]

A PRELIMINARY REPORT

WALTER V. BREM, M.D.
LOS ANGELES

It is true that any method of treatment of syphilis will be judged eventually by its power to prevent the development of the so-called parasyphilitic and metasyphilitic affections, and its power to eradicate the infection in the central nervous system, and thus to cure or to arrest the progress of the disease in those patients in whom the late nervous affections have already developed. The degree of improvement must always depend upon the extent and the location of the destructive and sclerotic changes that have already occurred.

It has now been demonstrated quite certainly that the parasyphilitic and metasyphilitic affections are phenomena associated with active syphilitic infection localized either in the central nervous system or in the bloodvessels. The demonstration has been made not only by finding the Wassermann reaction positive in the blood or cerebrospinal fluid in a very large percentage of such cases, but also by finding the specific organisms of syphilis in the brain (Noguchi and Moore[1]) or blood-vessel walls (Longcope[2] and others) in a considerable percentage of the lesions examined after death.

The problems concerning the nervous affections are, therefore, three:

1. To prevent the localization of the infection in the central nervous system.
2. To discover such localization, if possible, before the parasyphilitic phenomena have developed.
3. To eradicate the infection, thus permitting the processes of nature to restore and reeducate the patient to whatever degree is possible.

The first problem scarcely needs discussion, for any treatment that is effectual in eradicating an established infection of the central nervous system will be effectual in preventing the localization there. It need be said only that the earlier the diagnosis is made and treatment established, the surer will be the power of the treatment to prevent such localization.

MATERIAL, TECHNIC AND CONTROLS

My study of the two other problems is based upon an analysis of the examinations of ninety-six cerebrospinal fluids obtained from seventy patients, and on the treatment of fourteen of those whose fluids showed evidence of syphilis. The fluids of these fourteen patients have been examined thirty-eight times. All examinations were made with reference to pressure (measured in millimeters in a capillary tube), cytology, butyric acid globulin test, and Wassermann test. A Wassermann test of the blood, also, was made in nearly every instance. The cells were counted in a Zappert ruled hemocytometer after mixing equal parts of cerebrospinal fluid and 0.6 per cent. acetic acid. Noguchi's butyric acid test was made with 0.2 c.c. of cerebrospinal fluid. In the Wassermann test of the blood, the acetone-insoluble fraction of beef-heart was substituted as antigen in the Wassermann system, and 6 antigenic units used; the quantity of each reagent in the original test was reduced to one-fifth; an extra tube containing only one unit of complement with two parts of serum was added; and native antisheep amboceptor was titrated with each test.

Each cerebrospinal fluid was carefully titrated with ten tubes; the first two tubes were controls and contained respectively 1 c.c. and 0.4 c.c. of cerebrospinal fluid with one unit of complement; the third and fourth tubes corresponded to the two test tubes of the Wassermann reaction, and in each were placed two units of complement; in each of the remaining six tubes one unit of complement was placed and the tubes were given respectively 0.2, 0.3, 0.4, 0.6, 0.8, and 1 c.c. of fresh undiluted, unheated cerebrospinal fluid. It should be noted that 1 unit of complement is 0.1 c.c. of a 1 to 10 dilution of guinea-pig serum. (Each day the complement was titrated.)

This quantity used with 1 c.c. of fluid makes an exceedingly delicate test, and one that must be watched and controlled with great care. If the reagents are skillfully titrated, however, if the test is well controlled, and if the cerebrospinal fluid is tested within a few hours after being drawn, so that it does not develop anticomplementary properties, the results are perfectly reliable.

Non-syphilitic patients: In the series of seventy patients there were twenty-six that were probably nonsyphilitic. Wassermann tests of the blood were made in eighteen; all were negative even in the tube containing two parts of serum and one unit of complement. The cerebrospinal fluid of all twenty-four caused no fixation of complement, even in the tube containing 1 c.c. of fluid and 1 unit of complement. The pressure was obtained in thirteen instances and will be tabulated in a later report. The cells were increased above eight in two cases of meningococcus meningitis, one of acute poliomyelitis (240), and one case of probable brain tumor (11 mononuclears). The butyric acid test was strongly positive in meningococcus meningitis, poliomyelitis, one case of Pott's disease, and the case of probable brain tumor. It was definitely, though weakly positive in a case of arteriosclerosis and nephritis and was associated with a cerebrospinal pressure of over 340 mm. and blood-pressure of 228. The other tests were all negative or doubtful positives.

These twenty-six cases serve merely as controls for subsequent groups. There is nothing in them of especial interest except, perhaps, the case of nephritis and arteriosclerosis with high cerebrospinal pressure and a positive butyric acid test, and the case of brain tumor (not yet proved) with a strongly positive butyric acid test and a slight increase of mononuclear cells. Nine of the fourteen pressure determinations were 200 mm. or greater.

EARLY DETERMINATION OF SYPHILITIC LOCALIZATION IN THE CENTRAL NERVOUS SYSTEM

The cerebrospinal fluid has been examined in eleven cases of tertiary, latent and treated syphilis and in five cases of miscellaneous and atypical syphilitic cases. In the eleven cases, the patients showed no symptoms definitely pointing to organic nervous trouble. The Wassermann test of the blood had been or was positive in all. The examinations gave the following results:

Wassermann test, butyric acid test and cell-count positive	1
Wassermann test and butyric acid test positive and cell-count negative	3
Wassermann test negative, butyric acid test positive and cell-count negative	3
Wassermann test, butyric acid test and cell-count negative	4

---

[*] Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

[1] Noguchi and Moore: Jour. Exper. Med., Feb. 1, 1913, p. 232.

[2] Longcope, Warfield T.: Syphilitic Aortitis; Its Diagnosis and Treatment. Arch. Int. Med., January, 1913, p. 15.

One of these patients with an indefinite history of syphilis eleven years before, had had a nervous breakdown one year ago from overwork, "nervous prostration." He had continued in a "neurasthenic" condition in spite of rest and travel and symptomatic treatment. There were no objective signs of syphilis or of parasyphilis, but his blood-test was strongly positive, and all three tests of the cerebrospinal fluid were strongly positive—0.1 c.c. of the fluid fixed 2 units of complement.

A patient with paroxysmal hemoglobinuria had no nervous symptoms. His blood gave an intensely positive Wassermann reaction, 0.1 c.c. of a 1 to 300 dilution fixed 1 unit of complement. His cerebrospinal fluid was positive to the Wassermann and butyric acid tests, but it required 0.4 c.c. of the fluid to fix one unit of complement. This case is a good demonstration of the absence of relation between the Wassermann reaction in the blood and that in the cerebrospinal fluid.

A patient with Argyll Robertson pupils and double vision had no history of syphilis and no other manifestations of the disease. He was a strong robust man and seemed perfectly healthy. The blood Wassermann test was suspicious and the cerebrospinal fluid gave positive Wassermann and butyric acid tests and showed 35 mononuclear cells per 1 c.mm.

It is well known that syphilitic infections of the central nervous system are far more difficult to eradicate than when the infection is located elsewhere, and that the blood Wassermann is far more easily made negative than that of the cerebrospinal fluid. Considering these facts and cases like the ones above noted one is led inevitably to conclude with Neisser[3] that "one ought not to stop treating any syphilitic patient, even if the reaction in the blood is negative, without an examination of his cerebrospinal fluid. True alterations in the central nervous system can exist without clinical manifestations of any kind, but which, discovered by the serologic, microscopic and chemical examination of the cerebrospinal fluid may be treated, and thereby ultimate and perhaps incurable aggravations may be prevented."

In the examination of the cerebrospinal fluid we unquestionably have means of discovering in most cases, whether or not the infection has localized in the central nervous system, and one or more of the three tests may remain positive long after the blood Wassermann has become negative. It is fair to assume that those patients with positive cerebrospinal fluids are promising candidates for the later organic nervous affections of syphilis, and if it is possible to change the fluid to normal they should be treated until the desirable end is accomplished.

TABES DORSALIS AND GENERAL PARESIS

In the incipient and atypical cases of tabes and paresis the examination of the cerebrospinal fluid is invaluable for establishing the diagnosis, and in the advanced cases it is necessary as a therapeutic guide.

In my series there are nineteen cases of tabes with twenty-eight spinal fluid examinations; ten cases of general paresis with twenty-three spinal fluid examinations. A Wassermann test on the blood was made in all nineteen of the tabes cases and was positive only three times, (15.8 per cent.). The test of the cerebrospinal fluid was positive eighteen times, (94.7 per cent.). The butyric acid test was positive seventeen times in seventeen tests, (100 per cent.). Cell counts were made in seventeen cases; the number of cells varied from 10 to 128 in 12 cases, (70.6 per cent.) and was below seven in the other five cases. The pressure varied from 80 mm. to 300 mm. with a mean of about 220 mm.

In the ten cases of general paresis, Wassermann tests on the blood were made nine times with only three positives (33.3 per cent.). The Wassermann tests and butyric acid tests of the cerebrospinal fluid were positive in 100 per cent. of the cases. The cells were counted nine times and were above 10 in only three cases (33.3 per cent.). The pressure varied from 140 mm. to 350 mm.

There is a decided difference between the percentages of positive findings in my cases and those of other workers, my blood positives being fewer while my cerebrospinal fluid positives are more numerous. The discrepancy in the blood findings is due probably to the fact that in many of my cases an examination of the cerebrospinal fluid was requested by the attending physicians because the blood Wassermann was negative, while the discrepancy in the findings in the cerebrospinal fluid is due probably to the fact that my Wassermann titrations were carried much further than is usually done, making the test more sensitive.

TREATMENT OF SYPHILIS OF THE CENTRAL NERVOUS SYSTEM

There are no detailed reports in the literature, as far as I have been able to examine it, of syphilis of the central nervous system thoroughly treated and controlled by repeated tests of the cerebrospinal fluid. In the few cases that do appear, details are lacking as to the number of injections of salvarsan given, the size of the doses, the use of mercury, or the technic of the Wassermann test especially with reference to the most important point of the actual quantity of complement used. Only one author has spoken of titrating the "antibody content" of the cerebrospinal fluid, and though he states how much cerebrospinal fluid he used, I cannot tell the quantity of complement. If I have interpreted him correctly, the last tube in my titrations is ten times as sensitive as his most sensitive test.

Temporary symptomatic improvement in the parasyphilitic affections has been seen with mercury and the iodids, with one or several injections of salvarsan, and there have been remissions even without treatment. To be sure, therefore, that symptomatic improvement is unquestionably the result of treatment, one needs very convincing evidence. This can be supplied best by careful repeated examinations of the cerebrospinal fluid. My treatment has consisted in intravenous injections of salvarsan and neosalvarsan combined with mercurial inunctions or "mixed treatment" to the point of tolerance.

The intravenous injections of salvarsan have been given at intervals of six weeks to ten days, governed according to the reaction on the part of the patient and the reduction in the strength of the tests of the cerebrospinal fluid. Occasionally neosalvarsan has been substituted. The size of the dose has usually been 0.6 gm., excpting first doses which sometimes have been 0.4 gm. or 0.5 gm.

The details of the cases are shown in the accompanying table:

In the twelve cases showing definitely positive Wassermann tests in the cerebrospinal fluid the mean reduction in the strength of the reaction was about 50 per cent. for every three injections of salvarsan. I have made it a practice to examine the cerebrospinal fluid three to four weeks after every third injection. If treatment is effecnosis to become evident means a general dissemination of the virus with probably either visceral or central system involvement with their attendant burdensome and tedious treatment. The importance of lumbar puncture in cases of syphilis, which Dr. Brem has emphasized, is becoming more and more recognized. The frequency with which an involvement of the central nervous system is demonstrable during the secondary period of syphilis makes it practically imperative that such a condition should be ruled out by objective evidence. The early recognition of secondary syphilitic meningitis is of primary importance inasmuch as this condition usually persists over a long period of time and in the end may be responsible for the syphilitic lesions of tabes and paresis.

---

[3] Neisser: Les principes du traitement moderne de la syphilis, Rev. méd. d'Egypte, 1913, p. 9. Quoted by Henri Roger: Presse méd., April 6, 1913, p. 305.

Dr. R. C. Cabot, Boston: The brilliant work of Swift, at the Rockefeller Institute, New York, has not been referred to, nor the importance of treating these patients by salvarsanized serum injected into the spinal canal. Dr. Swift has used the cell-count, to which Dr. Brem did not refer, and has noticed after this method of treatment a diminished number of cells. We have been following out Dr. Swift's method at the Massachusetts General Hospital and have been impressed by the improvement in cases of tabes following the injection of the patient's own serum. After the patient has received salvarsan into his own blood, we bled him and 30 c.c. of his own serum are injected into the cord. The average dose, 30 c.c., given about once a week for a prolonged period, may strikingly ameliorate the condition of the spinal fluid, as found on puncture, and somewhat ameliorates the symptom.

It seems to me that the point which Dr. Brem has brought out, and which has been brought out by Dr. Dochez, is that we should make a spinal puncture in every case of syphilis.

Dr. F. F. Russell, Washington, D. C.: Dr. Brem has touched on one point, the examination of the cerebrospinal fluid in syphilis as a criterion of the cure of syphilis, and Dr. Cabot has just spoken of a standard of cure for syphilis. At present it seems to me that we might well talk about what shall be the standard of cure. We have four or five different tests to rely on, and it may be necessary to use them all; first, the length of time in which a man goes without symptoms; if a man goes without symptoms or a positive Wassermann, say for a year, that would be the first test; if at the end of that time he has a negative Wassermann, that is a second test; the third test would be a negative provocative Wassermann at the end of the year; the fourth test would be a negative luetin reaction. Dr. Brem and Dr. Cabot have proposed a negative cerebrospinal fluid, presumably at the end of the year. Thus we have five tests to be considered so that after a comparatively short time we can come to some agreement as to what shall be the standard of cure for syphilis.

Dr. A. J. Caffrey, Milwaukee, Wis.: Dr. Brem has had better results in fourteen cases of paresis than I have had in one case which I treated a few years ago. A man about 40 years of age gave a history of having had the initial lesion about seven years before. He had been treated at that time by a physician who later became paretic and is now in an insane hospital. He felt that his physician, who was insane, may not have cured him, and he had heard so much about salvarsan that he asked to have the treatment, which I gave him after having found a positive Wassermann. I gave the injection intramuscularly because at that time we were not using the intravenous method. Before he had the first injection, he had a morbid horror of approaching tabes; the examination showed no significant signs of tabes, but he had all the characteristic symptoms of incipient paresis. After the injection of salvarsan his condition improved for about eight days, but he lapsed back again into his morbid dread of approaching locomotor ataxia. I gave him a second injection after two weeks, but he became uncontrollable as an office case, so I sent him to a sanatorium where he attempted suicide by stabbing himself in the abdomen. I took him to the hospital and found that he did no damage to the intestine, the instrument having gone down between the coils of the intestine and slightly penetrated the omentum. He recovered from the wound completely and was ready to leave the hospital, but one day after he ate his dinner he fell over dead. Necropsy was refused, but I have always believed that the salvarsan set up some reaction in the brain which caused a blood-vessel to rupture.

Dr. James S. McLester, Birmingham, Ala.: In all cases of so-called parasyphilitic disease, my colleagues Dr. Ward and Dr. Toole, have followed the method of Swift. They first administer salvarsan intravenously, withdraw half an hour later a certain amount of blood and inject intraspinously 30 c.c. of serum so obtained. I cannot tell you their exact results, although I know in a general way that they are encouraging.

Dr. William Litterer, Nashville, Tenn.: The examination of the spinal fluid by the Wassermann test should be made in every case of syphilis before we can say that this disease is cured. I am greatly impressed with the Swift method in the treatment of cases in which a negative blood with a positive spinal fluid is recorded. This is certainly the logical means of treating these cases, especially since we know that very little salvarsan ever gains entrance to the subarachnoid space. This is due to the fact that the spinal fluid is a secretion and not a definite transudation. I have had only four cases in which I tried the Wassermann test with the spinal fluid, and I found that in one case only by the giving of salvarsan was I able to obtain negative results. The lymphocytes were decreased in all of these four cases, but I could not obtain a complete negative Wassermann except in one case. The other cases are under observation at present.

Dr. Walter V. Brem, Los Angeles: In my paper I should have discussed Swift's work, but my time was limited and inadvertently I did not refer to it. Swift's method of treatment may prove to be the method of choice. It is somewhat difficult, but if necessary it can be carried out. I am rather hoping that my method of giving the larger doses may prove as effective as Swift's. If it does it will, of course, be much simpler and be available for a much larger number of cases. I doubt whether there will be more danger attending it than there might be from Swift's method. The cerebrospinal fluids in our cases were examined with reference to pressure cytology, the globulin content and the Wassermann test, and all of these reactions must be negative before we feel safe. Dr. Russell brought out the fact that the spinal fluid should be examined at intervals during at least one year following cessation of treatment, and probably longer. That is the plan I am following at present.

THE VALUE OF ABDOMINAL MEASUREMENTS IN PREGNANCY *

A STATISTICAL STUDY

ALFRED BAKER SPALDING, M.D.
Professor Obstetrics and Gynecology, Stanford University Medical Department
SAN FRANCISCO

Since 1904 it has been customary for the assistants and students in my clinic at the San Francisco Maternity to measure the height of the fundus uteri above the symphysis in all cases of pregnancy. Measurements have been made with a tape-measure, placing one end on the upper border of the symphysis and the other on the ensiform cartilage. The uppermost margin of fundus of the uterus is located and read off the tape. In this paper, an effort will be made to estimate the value of these measurements in so far as they relate to the size of the unborn child and to the probable date for delivery.

Some years ago Ahlfeld[1] measured with a pelvimeter, the height of the fundus uteri in a series of cases and

[1] Ahlfeld, F.: Bestimmungen der Grösse und des Alters der Frucht vor der Geburt, Arch. f. Gynäk., bd. ii, 353, 1871.

concluded that from the twenty-fourth to the fortieth week the height of the fundus increased gradually from 15 cm. to 26.1 cm. He also made the valuable observation that while with the same measurement the weight of the babies varied, the length was very constant and was always twice the inter-uterine axis. But he did not associate these measurements with any rule for estimating the probable date for delivery.

Ahlfeld's work has been verified by Tramer,[2] Walraf,[3] Suttigen[4] and many others, but of late years so much attention has been given to estimating the size of the fetal head *in utero* by means of Muller's method of impression, or Stone's[5] modification of Perret's[6] method, that Ahlfeld's work has been neglected.

Chart 1.—Three hundred confinements. Height of fundus compared to weight of baby.

Suttigen[4] condemned the use of a tape-measure in measuring the fundus and stated very truly that the variations with a tape measure extended from 2 to as much as 13.5 cm. while with a pelvimeter, the variations were only from 2 to 5 cm. He observed that one of the chief causes for this variation was the contractions of the uterus. As the uterine contraction continues, the fundus rises higher and higher to subside at the end of the contraction to the original measurement. This is a very practical point and should always be taken into account in drawing conclusions from fundus measurements.

McDonald,[7] a few years ago, published a rule for estimating the period of pregnancy by measuring with a tape measure in a somewhat similar method to that which is described in the present paper but, unfortunately, his paper lacks statistical presentation and has overlooked the important point that as pregnancy advances the rate of uterine enlargement lessens. His rule is to divide the height of the fundus in centimeters by three and one-half in order to obtain the lunar month of pregnancy. About the same time I published a somewhat similar rule based on clinical observations, but also without statistical study. My rule was to add four to the height of the fundus as measured in centimeters, which would equal the probable week of pregnancy.

During the last five or six weeks of pregnancy it is surprising how closely both these rules will compare to Naegle's rule, but they both have the same basic error and are not accurate in the period from the twenty-fourth to the thirty-fourth week.

The literature is overburdened with many fantastic rules for estimating the weight of the unborn child such as that of A. Goenner, who stated that the weight of the unborn child could be estimated by measuring the foot, and such problems in mathematics as are presented by Roberts,[8] Tuttle,[9] etc.

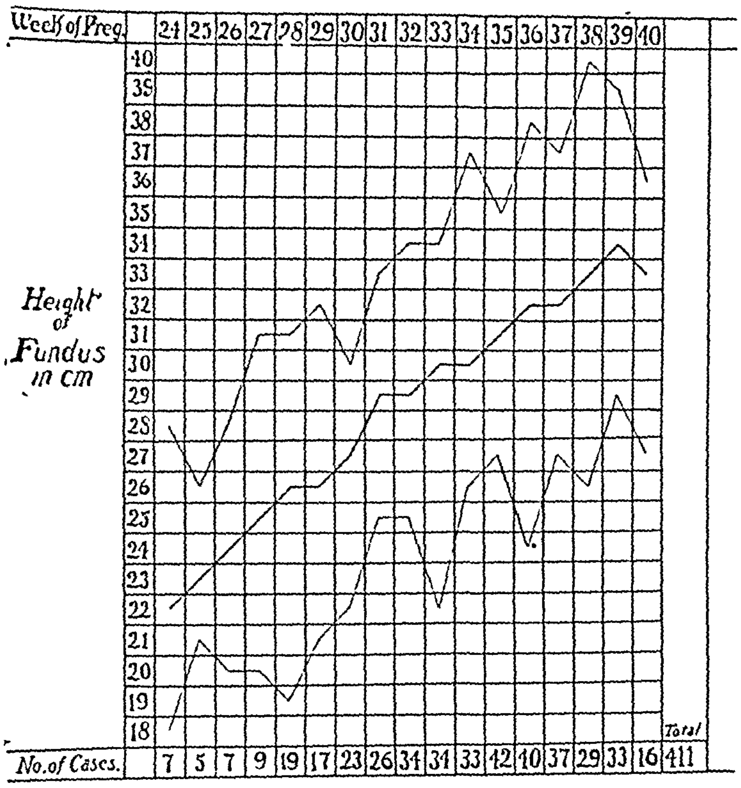

Chart 2.—Fundus measurements in series of 411 pregnancies. Upper and lower curves show limits of variations—middle curve shows average measurements.

Consequently, it is with many misgivings that the present statistical paper to estimate the value of uterine measurements is presented. Over two thousand records of confinement have been reviewed. On Chart 1 will be found the weights of babies taken immediately after delivery in a series of 300 labors where the height of the fundus and the degree of settling, or in other words, the total uterine axis was carefully observed. It will be noted that 157, or over half of the series, give fundus measurements between 34 and 37 cm. with average weights for the babies, between 3,275 and 3,395 gm. This might be considered a rough standard for average normal babies. Eighty-eight give fundus measurements between 38 and 45 cm., with average weights for the babies between 3,555 and 4,100 gm., besides five cases of twin delivery. This is a rough standard for over-maturity of the child. Fifty-five fundus measurements averaged betwen 2,175 and 2,930 gm. This also could roughly be stated as a standard of imperfectly matured babies. With experience, one can utilize these measurements to advantage in certain cases of toxemia, nephritis, heart-disease, etc., to determine the best period for the induction of premature labor or of the advisability of inducing labor at term; but unfortunately the possibility of error in exceptional cases precludes the utilization of these measurements in the management of contracted pelvis. It will be seen on the chart that with the same abdominal measurement, there is a variation in the weight of the child in exceptional cases of as much as 1 or 2 kilos. A great deal depends on the care with which the measurements are made, on the condition of contraction or relaxation of the uterus, on the skill of estimating the degree of settling and on the thickness of the abdominal walls, as well as the accuracy in diagnosing such conditions as hydramnios and multiple pregnancy.

Chart 2 presents the measurements of the uterus made at various weeks of pregnancy in a series of 411 patients. The patients in this series knew the date of their last menstrual period, gave birth to normal-weight babies within seven days of the expected time according to Naegle's rule and were not complicated with hydramnios or multiple pregnancy. The measurements begin with the twenty-fourth week of pregnancy and extend to the forty-first week. For each week the number of patients measured, which vary from five to forty-two, is stated on the charts. The upper and lower curves represent the greatest and the least measurements while the middle curve represents the average measurement obtained each week. The variations are the same that Suttigen noted and are due not only to personal equation, but to contractions in the uterus caused by manipulation of the fundus. I have tested this in personal cases and find that with a single examination these errors of variation are always possible, but with care and with repeated examinations at intervals, averages according to the middle curve are very constant.

Comparing these curves with the results obtained by Ahlfeld[1] and Suttigen[4] in a similar series of cases measured with a pelvimeter, it will be noticed that, even though the error of variation is less when measurements are made with a pelvimeter, the rate of increase noted from week to week is so small that no practical rule for estimating the period of pregnancy could be devised. In other words, measuring with a tape measure magnifies the results obtained with a pelvimeter (not only the errors but the averages as well) and permits of utilizing these measurements in a practical way.

In studying the curve of the averages, it will be noticed that there is a gradual increase in the height of the fundus from the twenty-fourth to the thirty-sixth week; after that, an irregular increase to the thirty-ninth week, and then a sudden drop to the forty-first week. The irregularity after the thirty-sixth week can be accounted for in the settling, which also causes some of the errors of variation noted throughout by the upper and lower curves.

Comparing the known week of pregnancy with the average measurements of the height of the fundus, it will be noted that between the twenty-fourth and twenty-eighth week or during the seventh month, the fundus measures 2 cm. less than the week of pregnancy; between the twenty-ninth and thirty-third week, or roughly the eighth month, the fundus measures 3 cm. less than the week of pregnancy; between the thirty-fourth and thirty-sixth week, or in the ninth month of pregnancy, the fundus measures 4 cm. less than the week of pregnancy;

[9] Tuttle, L.: The Relation Between Weight and Age in the Fetus, The Journal A. M. A., Sept. 9, 1908, p. 919.

and after the thirty-sixth week, or in the last month of pregnancy, the fundus measures 5 cm. less than the week of pregnancy.

Transposing these figures, it is easy to compute a rule for estimating an unknown week of pregnancy from the measurements of the height of the fundus. This has been done and has been found of considerable value, particularly in clinic patients, in whom so often no menstrual history can be obtained. The rule is: Measure with a tape measure the height of the fundus above the symphysis in centimeters, making allowance for settling when present, and add two to measurements between 22 and 26 cm., three to measurements between 26 and 30, four to measurements between 30 and 32 and five to measurements over 32, *which sum will equal the probable week of pregnancy.*

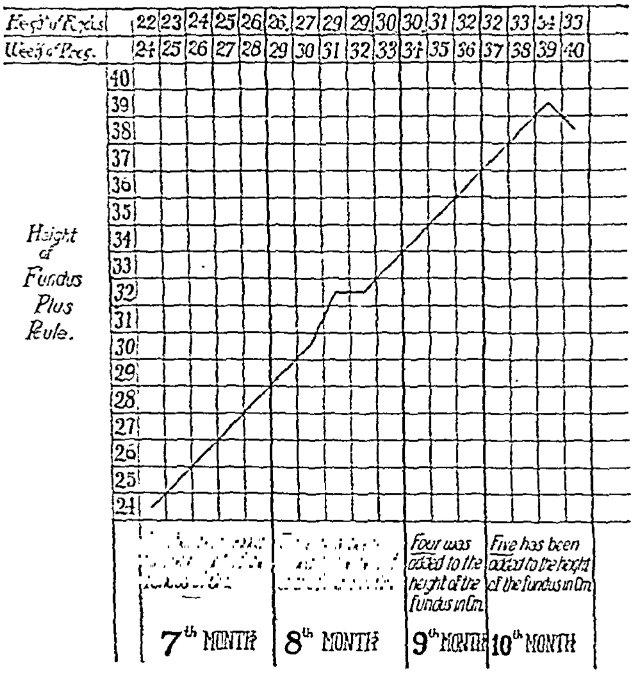

Chart 3.—Application of rule to measurements of Chart 2.

In Chart 3 the rule just stated has been applied to the measurements shown in Chart 2. It will be noted that with one exception, the estimated week of pregnancy corresponds exactly with the known week of pregnancy to the thirty-ninth week. It will be found that, with care, it is possible, as illustrated in this paper, to estimate accurately the probable week of pregnancy from the fundus measurements and in about three-fourths of all cases to estimate as closely as with Naegle's rule the date for the probable delivery.

CONCLUSIONS

Abdominal measurements are of value in estimating the degree of maturity of the unborn child. It is possible to estimate with considerable accuracy the probable week of pregnancy from accurate measurements taken with a tape measure of the height of the fundus above the symphysis.

Lane Hospital.

ABSTRACT OF DISCUSSION

Dr. Frederick E. Leavitt, St. Paul, Minn.: I have never accustomed myself to the use of the tape measure in the estimation of the size of the abdomen. I have depended rather on my own judgment and the estimate made from the manual examination. Dr. Spalding stated that in three-fourths of the cases it was possible in this way to estimate the date of labor correctly. From my own experience I think that I could strike it a little closer than that by estimating the probable date of labor from the date of the last menstruation. I do not see that there is any particular advantage in these abdominal measurements when we have accurate dates as to the last menstruation or the probable time of fertilization. The thing which interests me in abdominal measurements is to find out the proportions. The fetus is largely an unknown quantity, and in considering whether a patient is going to have a difficult or easy labor it is desirable to know how large the fetus is and whether or not it is out of proportion to the size of the mother. If the measurements indicated will help us, the idea is an advantage and of more importance than estimating the probable time of labor from dates. I have in mind several instances in which measurements of this kind would not have been of much value. In a family of two or three sisters and nieces there is a tendency to deliver short of full-term pregnancies. Some have gone thirty-four weeks, quite a number thirty-six, but none the full forty weeks. In these cases the measurements would not have helped to decide the date of labor.

Dr. E. Gustav Zinke, Cincinnati: A good obstetrician always regrets to accept a case of labor at, or just before, labor has begun. Some of the questions to be determined beforehand are: Is the patient pregnant? If pregnant, can she give birth to a child at full term? If so, what is the position of the child *in utero?* What is the general health and condition of the patient? And many other questions of great importance. Unfortunately, there are many who practice obstetrics who do not take the necessary care. It is this negligence which frequently gets both practitioner and patient into trouble. There is really no excuse on the part of the obstetrician, who is "engaged" long before labor, not to know the case before him and whether or not he will have a stormy time. Are the kidneys doing their duty? Are the emunctories of the body in perfect order? These queries bear significantly on the course and treatment of pregnancy and of labor. He who studies his cases carefully will not be taken by surprise.

Dr. A. B. Spalding, San Francisco: I think that we all realize how often women do not know the time of their last menstruation. I have seen a great number of charts which state that the labor is two months past the expected date for delivery. Again, when treating patients of a higher class—and the two classes that receive good service are the very poor and the rich—it will often be noticed that the pregnancy has run over the expected time for delivery. When pregnancy runs over, we should measure the height of the fundus as well as the pelvis. These measurements are of particular value in the class of patients who rest and eat too much. We have at our disposal good methods for the induction of labor at any time we desire, and that time should be when we think the child is large enough to survive and small enough to do the least injury to the mother's genital organs. In patients with habitual short-term pregnancies, we can measure the baby *in utero* and if we find that it is too small we can overfeed the mother and get it up to a normal weight. The operation for preventing prolapse of the uterus is of great interest to all of us. One of the best methods to prevent prolapse is to measure the abdomen every two or four weeks during the latter weeks of pregnancy, in order to know when the baby is fully developed and, at the same time, not so large as to cause serious injury to the woman's organs during labor, which will require subsequent serious surgical work or, more often, years of misery for the woman. It is the shame of obstetricians that so many of these cases go to the gynecologist afterward. There is no reason to my mind why patients should leave the hands of the obstetrician with damaged or diseased abdominal or genital organs if he does his work completely and properly. That is why I have presented this simple obstetrical paper. It is in the hope of encouraging enthusiasm for prophylactic gynecologic work rather than enthusiasm for repair work on women after years of misery due to poor obstetrics.

THE ESSENTIALS OF SANATORIUM TREATMENT OF TUBERCULOUS GRAVIDAE AND PUERPERAE AND THEIR CHILDREN *

CHARLES S. BACON, M.D.
CHICAGO

There are about 32,000 tuberculous women pregnant every year in the United States. Between 44,000 and 48,000 women of child-bearing age die of tuberculosis every year. Probably one-fourth of them are puerperae or have passed through pregnancy during the year, or, in other words, the gravidae and puerperae furnish one-fourth of all deaths from tuberculosis of women of child-bearing age. From this it also follows that about one-third of the pregnant tuberculous women die within a year of their labor. Of 10,000 children under 5 years of age who die of tuberculosis every year, three-fourths are born of tuberculous mothers.

These data show a part but not all of the bearing of pregnancy on the tuberculosis problem. Besides the increased loss of life among the tuberculous due to pregnancy, there is increase of infection both among the attendants, relatives and associates of the mothers and among the children. The gravidae and puerperae constitute an important factor in keeping alive the germ of tuberculosis and preventing the eradication of the disease. This factor has not been sufficiently recognized in the past, if we consider the means hitherto employed to combat it as an index of the general appreciation of the importance of the factor.

The proper management of the tuberculous gravida and puerpera and her child is that which carries the woman through labor and the lying-in period and leaves her from two to four months later in as good condition as she would have been in had she not been pregnant, and presents the child at that time to its parents and to society uninfected. This means considerably more than the ordinary care received by the average obstetric patient. It means a close watch of pregnancy, conservation of the strength of the patient and timely interference if necessary. It means the most skilful conduct of labor, through which the patient passes with no unnecessary loss of blood or of strength and with no risk of infection. It means a supervision of the puerperium to prevent as far as possible the exacerbation of the disease which is so common at this time. It means the separation of the child from the mother and caring for it as long as necessary. If the child is premature or feeble, incubation may be required at first. An incidental but very important feature of the management thus outlined is the education of the mother and her relatives.

We are of course considering only cases in which there is no therapeutic interruption of pregnancy. Possibly in 10 per cent. of all pregnancies in tuberculous women, or in 3,000 a year in the United States, therapeutic abortion is indicated. In the very great majority of cases, however, we must face the problem of a proper conduct of these patients through labor and the puerperium.

The obstetric management above outlined can be carried out in a private house only with considerable difficulty. It requires in the obstetrician peculiar skill, training and patient persistence. It demands likewise similar qualifications in the nurse. It is possible only among well-to-do patients who are sufficiently intelligent to agree to the regimen required. Probably not more than 10 per cent. of the 32,000 tuberculous gravidae found yearly in the United States could be ideally managed in their homes.

The labor can be conducted better in a maternity hospital or in the maternity department of a general hospital than in the home, but the conduct of the latter part of pregnancy and a long puerperium, which are at least as important as the conduct of labor, cannot be provided in such a hospital. Moreover, hospitals hesitate to admit patients infected with tuberculosis.

Hence comes the necessity for a maternity department in the tuberculosis sanatorium. We believe that three-fourths or even nine-tenths of all tuberculous gravidae should be cared for in such sanatoriums, and we insist that such care is necessary for at least one-third of these patients in order to protect them and society. This would mean that in the United States about 10,000 tuberculous gravidae should be sent to sanatoriums. To show the need of institutional treatment of the poor it might be stated that about eighty to one hundred pregnant women are included in the 8,500 patients who last year applied to the dispensary department of the Chicago Municipal Tuberculosis Sanatorium. All of these pregnant women should be cared for during the latter part of pregnancy and for some time after labor in a sanatorium.

Up to the present time there has been no provision made for these patients either in this country or in Europe. On the contrary, all institutions have practically excluded pregnant women. In the United States among the 30,000 to 40,000 hospital beds for consumptives not one is available.

This situation is probably due in part to the fact that hitherto this feature of the tuberculosis problem has not been emphasized, and in part to the supposed difficulty of providing a maternity department in connection with a general tuberculosis sanatorium. It is especially the object of this paper to call attention to the ease with which such a department could be provided. The essentials of sanatorium treatment are few and simple and not expensive. They can be provided in any large institution with little trouble and cost. Every state or municipal institution should certainly supply them, for the patients coming to these institutions are especially in need of sanatorium care. Many of these patients already have one or more small children. This is one of the great difficulties in securing proper sanatorium care for them. The mother cannot and will not leave her little children at home or elsewhere to the care of relatives or friends. Careful examination will show usually that the children are already infected. Any adequate solution of the problem must provide for these children.

The Chicago Municipal Tuberculosis Sanatorium which is now under construction has provided an obstetric department that may be taken as an illustration of what can be accomplished without making any material change in the plans of the institution. This institution is located in the outskirts of the city on a half section of land and will provide for 850 patients. Through the center of the grounds extend the four main buildings, the administration building, dining rooms, the infirmary and the power-plant. On each side are located about twenty open-air cottages, those for the women being on the right hand or south side. The infirmary is a two-story building built in an H-shape, the south side being used for the women. In the infirmary are housed the patients that are unable to be around. In this infirmary is located the nursery and confinement room of the

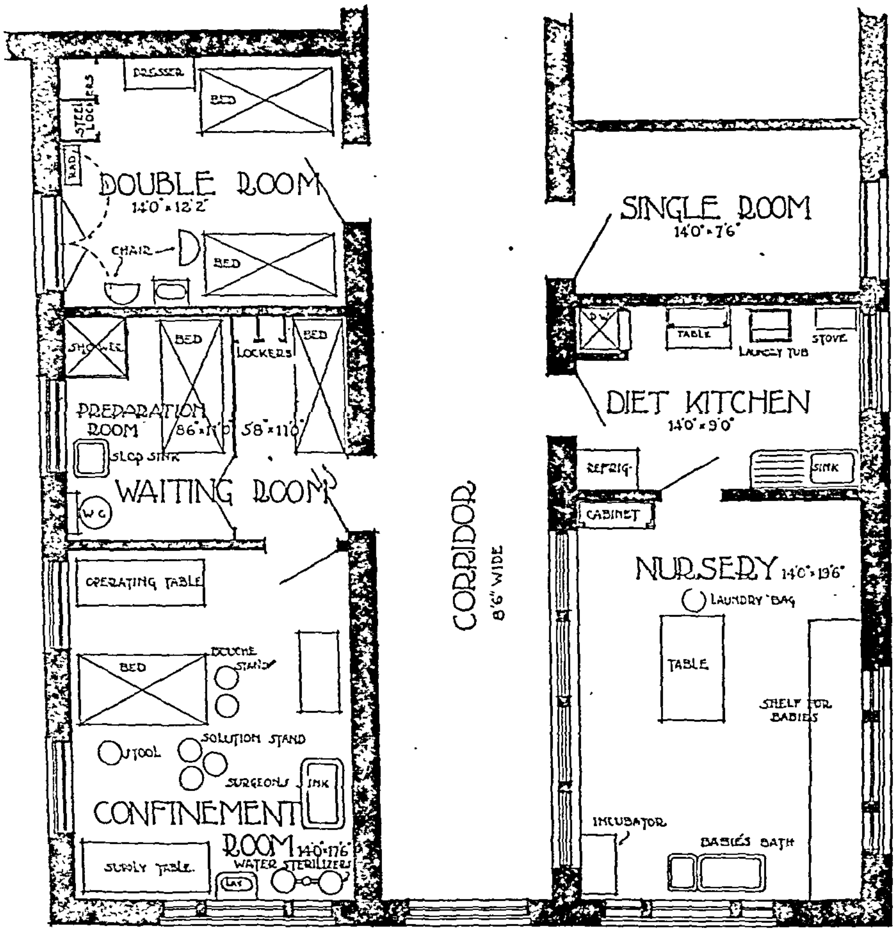
---

* Read in the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

maternity department, as well as the rooms for small children.

Before describing the arrangement further let us consider what is needed in the maternity department of a tuberculosis sanatorium. Five things will be required: (1) provision for gravidae; (2) a confinement room; (3) provision for puerperae; (4) a nursery; (5) a *children's department.*

Both gravidae and puerperae can be housed in the cottages or in the infirmary. If the pregnant women are able to walk around they can remain in a cottage near to the infirmary. The only especial provision required is, perhaps, that they be provided with an exercise place that is somewhat secluded, and this can be done by fencing off a section of the grounds with shrubbery. As soon as a puerpera is able to be around she may also go to a cottage.



Plan of maternity ward infirmary group, City of Chicago Municipal Tuberculosis Sanatorium.

The confinement and preparation rooms are like similar rooms in any hospital and are necessarily located in the infirmary.

The children's department, where the small children of the gravidae will be kept, is on the second floor of the infirmary above the obstetric department. There are rooms, wards and sun parlors in the porches so planned that the more serious cases can be separated from the light or doubtful infections.

The essential feature of the plan is the nursery. This should be on the sunny side of the building and should be well heated and ventilated. It should be separate from the mothers but located near them. It should provide at least 16 square feet of floor space, or 160 cubic feet of space, for each baby.

A study of the plan will show how these features are provided in the nursery of the Chicago institution. Two rooms, a nursery 14 by 20 feet and a nursery diet-room 14 by 9 feet, are located in the southwest corner of the women's part of the infirmary. To separate the babies from the mothers and yet keep them contented is the difficult problem. This is accomplished by having a glass partition between the corridor and the nursery so that the mothers can see their babies during the bathing or at any time.

The heating plant will furnish the nursery any degree of heat required. An incubator will be installed for premature or especially feeble babies.

In feeding the babies it is planned to utilize the mother's milk as much as possible. Inoculation and other bacteriologic tests of the milk will be made to determine whether the milk from a mother is free from tuberculosis germs or not. In case it is safe, and if the condition of the mother allows lactation, her milk will be obtained by hand milking or with a pump. This milk will be preserved in the diet room and fed to the child, supplemented by such artificial feeding as may be required.

This nursery will hold about eighteen babies, allowing each over 16 square feet of floor space and 176 cubic feet of space. Mothers and babies should be kept three months, and this would give a capacity of about seventy-two patients a year. If the mothers can be induced to remain only two months, as will probably be the case, the capacity of the nursery will be 108 a year. The capacity for gravidae and puerperae is unlimited, because any of the beds of the institution can be used by them. It is predicted that the applications for the first year or two will be about 100, or about one-eighth of the tuberculous gravidae of Chicago. Later, if the number increases, the nursery can be enlarged by using the adjoining rooms on the other side of the diet-room.

Eventually it may be desirable to erect a separate building for the maternity cases. The space provided in this pioneer plan, and also the equipment, is the minimum. Of course it is not pretended that an ideal nursery is provided. It is claimed that for the cost it is sufficient and eminently practical.

The accouchement room, with the adjacent preparation room and waiting-room, can be used not only for confinements, but also for induction of abortion when this operation is indicated. Other clean obstetric or surgical operations might also be made in this room in order to utilize it to its fullest extent.

In the hygienic and dietetic management of the pregnancy and the puerperium the same principles apply as in the management of any other tuberculous patient. Rest, massage, respiratory and general exercises, recreation, sleep, feeding, control of excretions, all must be acromegalic changes, such as a thickening of the bone, enlargement of the sinuses, mandibular prognathism, etc.

Especial attention should be called, according to Schüller, to the development of the so-called sphenoparietal sinus—a venous channel connecting the sinus cavernosus with the convexity of the skull. In big tumors of the sella this sinus is often enlarged, which can be explained by pressure of the growth on the sinus cavernosus. In normal persons, however, one must remember that a large sphenoparietal sinus is occasionally to be found; so that this condition must always be interpreted with a certain amount of caution.

In tumors of the acoustic nerve, a rather characteristic change in the dorsum sellae has been observed. These tumors sometimes produce not only a thinning of the dorsum sellae, as in other extrasellar growths, but also a rather characteristic tendency of the dorsum sellae to incline forward. This fact enables us at times to make a diagnosis of an acoustic tumor from the roentgenogram, especially when these changes of the sella are combined with the described enlargement of the meatus acusticus (Henschen).

All these examples show that changes of the sella turcica in size and shape occur rather frequently in conditions other than true pituitary tumors; that is, in tumors in the neighborhood of the sella turcica as well as in tumors without any topographic relationship to the hypophysis and in cases of increased intracranial pressure due to internal hydrocephalus. On the other hand, the great influence of the other ductless glands on the development of the pituitary gland and on the secondary changes of the sella turcica has been demonstrated. These facts prove that not every change in the sella turcica is necessarily to be interpreted as a result of a primary pituitary disease, a fact which I hope I have emphasized especially in these brief remarks.

A COMPARATIVE STUDY OF ANTIGENS FOR THE WASSERMANN REACTION[*]

H. R. VARNEY, M.D.
AND
F. W. BAESLACK, M.D.
DETROIT, MICH.

HISTORICAL REVIEW

In 1901, Bordet and Gengou published the method for complement fixation, which was designed for the purpose of detecting antigens; that is, such bodies as are capable of producing antibodies, as well as a definite group of serum substances, probably amboceptors, the nature of which is not yet determined. It is possible by this method to determine, by the use of a known antigen, whether a certain serum contains the specific amboceptor, or reversely, one may determine by means of a known serum whether the substance used as antigen contains the antigen bodies. Neisser and Sachs proposed the use of this method for the differentiation of albumin. Wassermann, Neisser and Brück were able to demonstrate, in the serum of monkeys which had been previously treated with extracts of syphilitic organs, the presence of substances which gave complement fixation with syphilitic extracts. Detre, as well as Wassermann, Neisser, Brück and Schucht, found the same substances in the serum of syphilitic patients. Their early experiments, however, gave very inconsistent results. Citron was the first to recognize that the amounts of antigen and serum employed by the former authors had been too small and that the influence of the specific medication on the reaction was unknown to them.

Porges and Meier, von Landsteiner, Müller and Pötzl and later Yamanouchi and others pointed out independently that a substance could be obtained by extracting syphilitic and normal human liver as well as other organs with alcohol, which, when mixed with the serum of syphilitics, gave rise to complement fixation, and which to a certain degree could replace the syphilitic antigen. Porges and Meier, as well as Landsteiner, incline to the view that the alcohol-soluble substance is a lipoid closely related to lecithin, while Levaditi and Yamanouchi ascribe less significance to the lecithin and consider the bile salts as the important substances. The complement-fixation tests carried on by Wassermann and Citron with various colloidal substances such as glycogen, albumoses, peptone, lecithin, oil and gelatin, as well as the experiments of Landsteiner and Stanovic with other colloids, led Citron and Wassermann to the assumption that the cause of the complement fixation is a chemicophysical change of the molecule due to its entering into combination with some other substance. The experiments of Seligmann also prove that in colloidal reaction with or without precipitation complement may be absorbed. The disappearance of the complement is not due to the molecular condition as such, but is due to the changed condition of the colloids. While this does not offer any explanation of the specific immunity reaction, it shows that aside from the immunity reaction there coexist other definite chemical reactions which cause the disappearance of the complement. This in no way alters the great value of the complement-fixation test for the biologic diagnosis of infectious diseases, for it is the special property of immune serums to influence to a greater degree that colloid which is their antigen.

These findings induced Wassermann to separate the complement fixation in syphilis from the generally accepted antigen-antibody hypothesis for other infectious diseases, for he assumed that all antigens must be albumins or derivatives of albumins, without considering that some lipoids or lipoid-albumin combinations might be antigens also. The experiments of Metchnikoff and those of Deyke Pasha and Reschad Bey point to the fact that it is possible to stimulate the organism to the formation of reacting agents, similar to antibodies, by the injection of fat-like substances. The cobra-lecithin experiments should also be mentioned in this connection. It was pointed out by Citron that the injection of animal and other poisons with lecithin causes the formation of toxolipoids which may act as antigen, that is, produce antibodies. Such antibodies against the syphilitic toxolipoids may have a lipoidophil group which is brought out in the admixture with lecithin.

The fact that the serums of luetic patients are rich in ferments capable of splitting certain fats and lipoids and the presence of such ferments to a lesser degree in the serums of patients suffering from other infectious diseases, such as leprosy, tuberculosis, scarlet fever, etc., may be the reason why such serums react with syphilitic antigen. Thus it is possible that in the Wassermann reaction we are dealing with several distinct complement-fixation reactions of entirely different character, one of which may be specific.

In spite of the fact that the Wassermann reaction is as yet unexplained, it is widely used for the diagnosis of syphilis. The aqueous extracts of the syphilitic liver and spleen were, on account of their instability, displaced by alcoholic extracts of these syphilitic organs. The difficulty of obtaining syphilitic fetal tissue also had its influence in stimulating the search for some substitute as antigen. More recently acetone has been employed as extractive, because it is supposed that such extracts contain substances which approximate the syphilitic antigen more closely, and thus permit of a more delicate reading of the test. It does not fall within the scope of this paper to review the extensive literature dealing with the various antigens employed by the experimenters in this field of research. The extracts employed have been either specific, such as were obtained from syphilitic tissues by the use of water, alcohol, or acetone as extractives, or they have been non-specific extracts made from heart muscle, liver and brain of guinea-pigs and cattle. Aside from these extracts, combinations of chemical substances, such as Schurmann's and those given by Sachs and Rondim, have been employed as antigens in this reaction. From this it appears that normal tissue contains substances, possibly to a lesser degree, as has been shown by Much, which have the power to absorb the complement.

---

[*] Read in the Section on Dermatology of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

Aside from the use of artificial antigens, there have been other modifications of the Wassermann reaction; however, none of these modifications have as yet increased the clinical value of the test, nor has any attempt to simplify the method been suggested which does not at the same time sacrifice considerably its accuracy.

In the course of the inoculation experiments of four strains of the *Spirochaeta pallida,* which have been carried on in rabbits at the Research Laboratory of Parke, Davis & Co., it seemed that the white, glistening gumma, which contains practically nothing but spirochetes and the products of their metabolism, might offer material for the preparation of antigen for the Wassermann reaction which would possess more of the specific antigen bodies than any other antigen yet used for such purposes. The antigen thus prepared was made from lesions caused by the four strains of the organisms. We had, therefore, a specific and to some degree polyvalent antigen. The four strains of *pallida* have been transplanted now for over a year, and the lesions which these organisms produce are free from secondary infection. No antigen was prepared from cultures of the organism, since the culture does not afford a sufficient amount nor could the mediums in which the *pallidae* were growing be separated from them. It seemed that the extract of organisms and culture mediums would afford us no more specific antigen than had been employed by others thus far. The syphilitic gumma frequently replacing one half and more of the testis seemed better suited for this purpose, since all the non-infected tissue could be trimmed away, and only the grayish-white gumma used. The term "gumma" is here used not in its strictest sense. The lesion produced by the action of the *pallida* in the gland proper is one of clearly circumscribed mucoid degeneration. Superficial chancres were not employed since these are usually contaminated with other bacteria.

The antigens were prepared as follows: The lesions were carefully freed from the tissue not involved, ground up fine and weighed. The material was then frozen in an ice and salt mixture, and dried *in vacuo* over sulphuric acid. When completely dry, it was placed in physiologic salt solution to which 0.3 per cent. trikresol had been added. The ratio of tissue to salt solution is 1:4. This tissue suspension was shaken for twenty-four hours and placed in a sterile amber glass bottle in the refrigerator for three days to allow the tissue to settle. This was our aqueous antigen.

The alcoholic antigen was prepared in the same way that the regular stock syphilitic fetal liver antigen is prepared.

The acetone extract was prepared by placing the ground-up and dried tissue into Merck's C. P. acetone, taking for every gram of tissue 20 c.c. of acetone. This was allowed to stand in a dark bottle at room temperature for eight days, filtered and evaporated at 37 C. (98.6 F.).

The residue was taken up with C. P. methyl alcohol, one hundred parts of the methyl alcohol being used for every gram of residue. The acetone residue contains a substance which is not soluble in methyl alcohol. The methyl-alcohol-soluble extract is admixed with ten times its volume of physiologic salt solution for the test.

These three extracts of gumma of rabbits were tested against the alcoholic extracts of syphilitic fetal liver, and in our last experiments, the acetone-insoluble portion of beef heart.

Practically every antigen has the power to bind some complement. And the reason for the diversity of results obtained by some investigators on one and the same serum does not lie so much in the method employed as in the proper titration of the extract employed as antigen.

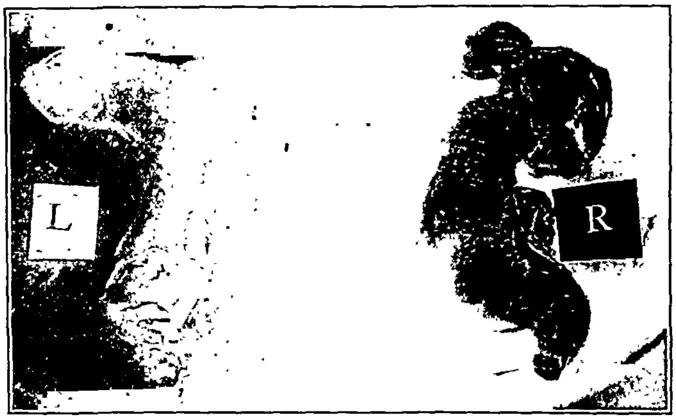


Fig. 1.—Syphilitic gumma of testis of rabbit from which antigen was prepared.

The value of a certain extract is usually determined by a preliminary experiment, usually according to Wassermann, in which a unit of the antigen gives complete fixation when admixed with a unit of luetic serum, while normal serums give a negative reaction. Any antigen fulfilling these requirements is considered satisfactory for this reaction.

If increasing doses of an antigen are tested for their activity in the seroreaction in syphilis, then it is shown that very small amounts will not bind the complement even in cases of florid syphilis. As the dose of the extract is increased, the fixation of the complement occurs with greater frequency, so that serums of latent syphilitics also react. If the amount is increased still more, the serums of patients not syphilitic will give positive reactions. And if the dose of the extract is carried still higher, we find that serums of normal healthy individuals give the reaction. The amount of antigen is then able to bind all the complement. It thus becomes evident that only such amounts of antigen should be employed in syphilis as will bind the complement only with luetic serums. Thus the Wassermann reaction is specific only within certain limits of the doses of antigen. For this reason the extracts were tested for their power to bind complement.

Increasing amounts of the extract are placed with the amount of complement usually employed in the sero-reaction in the incubator, then amboceptor and sheep blood corpuscles are added. For the test only one-half of that amount is used, which clearly indicates fixation (*Eigenhemmung*).

DETERMINATION OF THE SENSITIVENESS

In the serodiagnosis of syphilis, it is not so much a question of obtaining fixation of complement with undoubted cases of syphilis, as of determining a fixation of complement in the doubtful cases, which determine for or against syphilis. Complete binding of the complement is practically uniform with all extracts, but the cases demanding especial attention are those which show only partial complement fixation. Such cases may be overlooked by an observer who does not work with a sensitive antigen, for which reason it is not advisable to take the serum giving a strongly luetic reaction, for a positive control, but one which lies on the border-line, that is, serums that give a weak positive reaction, such as latent luetics, and those having sclerosis. Such serums are tested with varying amounts of extract according to the usual method, beginning with minute dilutions of antigen to the largest permissible.

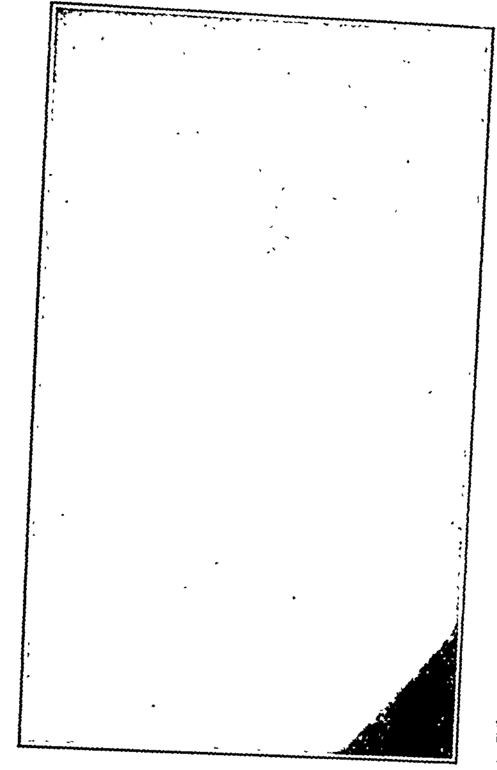

Fig. 2.—Luetin reaction obtained from gumma in rabbits used for the preparation of antigen. Control in center.

DETERMINATION OF THE SPECIFICITY

It is evident that for this purpose not only serums of normal individuals should be employed, but also serums which, from experience, at times give a positive Wassermann reaction. It has already been pointed out that in such cases we may not be dealing with the same biologic process which takes place in the serum of a luetic, but with a non-specific process which simulates the specific reaction in syphilis. Many serums from cases of various general diseases contain substances which inhibit hemolysis. If to such serums antigen is added which also contains bodies capable of binding complement, we are able to observe a summation of these two binding substances which absorb all the complement.

The specificity of the antigen used was determined by the luetin reaction, in so far as this reaction may be called specific. Extract of the gumma gave positive reaction in tertiary cases of this disease.

These comparisons of the antigens of gumma cover only the preliminary stages of the work we have begun. The antigens prepared from the several strains of the spirochetes are more active and for this reason had to be diluted from ten to twenty times more than the ordinary antigens prepared from syphilitic fetal organs or normal tissues. This high dilution of the antigen minimizes the physical influence, which strong alcoholic antigens exert on the serums to be tested. The antigens when admixed with physiologic salt solution were practically clear, differing in this respect from other antigens which in dilution show milky white turbidity. Another difference noticed between the rabbit gumma antigen and other antigens is the more delicate reading of the results of the reaction. The cases of doubtful clinical diagnosis are more clearly brought out by these antigens.

The sensitiveness of these antigens to luetic serums led us to test them against serums from leprosy and scarlet fever. Through the kindness of Dr. Guy L. Kiefer, health officer of Detroit, we were able to obtain serums from scarlet fever patients while the disease was in its eruptive stage and at different periods following this stage. The leprosy serums included were obtained through the courtesy of Dr. James MacFarlane Winfield of Brooklyn, to whom we desire to express our thanks.

The syphilitic lesions in rabbits permitted us to obtain antigens which to a degree are more specific than the antigens generally employed, since these gumma contain the spirochetes in large numbers free from contamination. At the same time we were reasonably certain that our antigens were free from the bile salts which possibly are present in the antigens made from fetal syphilitic livers.

The fact that Schwartz and McNeil were able to improve the fixation of complement in gonorrhea by combining twelve strains of the gonococci of their antigen led us to combine the four strains of the *pallida* for the antigens we employed. By so doing, we increased the efficiency of the antigens. The reaction was negative, however, in the serums of patients having just passed the eruptive stage. The serums of leprosy patients were also positive, yet to a less degree than the luetic controls. How far this reaction is due to the leprosy per se, it was impossible for us to determine.

SUMMARY AND CONCLUSIONS

1. The use of syphilitic gumma in the testis of rabbits yields a more specific antigen than any obtained from other syphilitic or normal tissue.

2. The combination of a number of strains, giving a polyvalent antigen, increased the value of the antigen, permitting the diagnosis of clinically doubtful cases.

3. Aqueous antigens lose their strength in about one month while those prepared with acetone and alcohol are stable.

From our data, we incline to the view that in the Wassermann reaction of syphilis, we may be dealing with three distinct reactions. First, we deal with the antibodies produced against the causative organism—if such antibodies are produced; next, we are dealing with substances, possibly antibodies, directed against bacterial lipoids, and, finally, with a group of substances, autolytic in nature, which the tissues of the body evolve against the toxic substances resulting from the influence of the *Spirochaeta pallida* on the tissues.

Washington Arcade.

ABSTRACT OF DISCUSSION

Dr. Howard Fox, New York: The antigen is the all-important factor in the Wassermann reaction, but the attempts that have thus far been made to standardize our preparations have not been particularly successful. It would be a great step in advance if we could find a standard antigen which every one could use, as in that way there would be fewer divergent results from different laboratories. During the past year I have used the alcoholic extract of normal heart, titrating the complement and using decreasing amounts of the serum of the patient. By this method I have obtained better results than I did formerly with the alcoholic extract of fetal liver.

Dr. J. Frank Waugh, Chicago: There is one other antigen which I do not think has been mentioned. Noguchi has done a great deal of work on the serodiagnosis of syphilis, and in one of his articles on the subject he mentions an insoluble acetone antigen. Dr. Harris gave me some soluble acetone antigen, and on testing it, I found it very efficient. The acetone extract gives a stronger reaction in some cases than the alcoholic extract. In the last year I have tried and compared both the alcoholic and the aqueous extracts with the acetone extract and have found the latter just as efficient. I agree with Dr. Fox regarding the importance of a strong, standard antigen.

In the *Deutsche medizinische Wochenschrift* (Dec. 5, 1912), O. Stiner reported his experiences with the use of acetone extracts. He reports that in some cases of positive lues, in which alcoholic extracts gave negative results, positive reactions are secured with an acetone-liver extract.

Dr. M. L. Heidingsfeld, Cincinnati: I take exception to Dr. Varney's statement that the gonococcus complement-fixation test is more reliable than the Wassermann, in order to spare the Wassermann too much undeserved disrepute. Theoretically, the gonococcus test should be more reliable than the Wassermann, but experience has shown that the Wassermann is far the more reliable of the two. The Wassermann never errs on the unsafe side, and is a reliable procedure if the details are carefully and properly carried out. As Wassermann has pointed out, there is a fundamental reason for every step of the reaction. Some of the modifications may be more delicate, but they are at the same time the less reliable.

Dr. Rudolph Buhman, St. Louis: Did Drs. Varney and Baeslack use a watery or an alcoholic preparation as an antigen?

Dr. H. R. Varney, Detroit: I thoroughly agree with Dr. Fox that what we are searching for is a standard antigen, and that when it is found we shall have more uniform laboratory reports. Regarding the preparation of the antigen, the aqueous, acetone and alcoholic were used and checked up in series.

Regarding my estimate of the comparative accuracy of the Wassermann and the gonococcus fixation tests, which Dr. Heidingsfeld criticized, I would say that, so far as I have been able to follow the laboratory records, I am able to assert that by the fixation test it is possible to pick out the diplococcus of Neisser from a large family of similar organisms, which is proved clinically, while with the Wassermann test we cannot with our present knowledge positively exclude other diseases, as tuberculosis, scarlet fever or leprosy.

Dr. F. W. Baeslack, Detroit: The delicacy of the test depends largely on the titration of the antigen. We may titrate for its delicacy and sensitiveness, and it is only when tested against weak syphilitic cases that a real idea of the value of the antigen is obtained. It is in the careful titration of the antigen that the secret lies, and what we are searching for is a reliable antigen.

Suggestion and Disease.—It is undoubtedly true that a serene spirit is a valuable agency in the recovery from disease. It is likewise true that suggestion has a mighty potency when it is rightly applied. It is a legitimate and recognized branch of therapeutics, which may be destined to have a wide application in the future treatment of disorders of the nervous system. But it is likewise true that suggestion heals no broken bones, a spirit unperturbed gives no safeguard against poisoned mosquitoes, and the power of the will and the imagination is potent chiefly against disorders of the imagination and the will.—David Starr Jordan, *Science.*

CLINICAL OBSERVATIONS ON THE EMETIC ACTION OF DIGITALIS[*]

CARY EGGLESTON, M.D.
NEW YORK

Nausea and vomiting are probably the commonest of the side-actions encountered in the clinical use of the digitalis bodies. They have generally been attributed to a local irritant action of these substances on the mucous membrane of the alimentary canal. In two previous papers[1] Dr. Hatcher and I have shown that the digitalis bodies cause nausea and emesis in animals through their direct action on the vomiting center in the medulla. We have been unable to find in the literature, or to adduce from our own experiments, any evidence either to controvert this statement or to support the opposite view of local irritant action in the stomach or intestine. In view of our experimental findings we called attention to the need for a carefully controlled series of observations on the seat of the emetic action of therapeutic doses of this group of drugs when used clinically. It is the purpose of the present paper to set forth the results of such a series of observations, together with a review of several series of cases reported in the literature in other connections, and to correlate the clinical and experimental data as far as possible.

Fifteen cases of cardiac valvular disease were studied in the wards of Bellevue and New York Hospitals.[2] In all but one of the cases the clinical observations were supplemented by the use of the polygraph. None of the patients received other medication which might in any way influence the actions of the digitalis, except Nos. 4 and 6, who received tincture of nux vomica, and Nos. 6, 10 and 13, who were given atropin, with a view to studying the modifying effects of these drugs. A brief summary of each case follows, fibrillating and non-fibrillating cases being considered separately.

In the summaries, and in all of the tables, the expression "clinical improvement" is used for brevity, and by it is meant clinical evidence of definite improvement in those symptoms referable to impaired cardiac action.

Case 4.—B. H., No. D. 2, 417. Woman, aged 65. After taking 1.6 gm. of digitalis in the form of tincture, m. x, q. 4 h., vomiting began. Tracings showed slowing and coupled rhythm. Marked clinical improvement preceded the vomiting. The digitalis was continued together with m. x of tict. nux vomica, but the vomiting continued and both drugs were stopped. After an interval of five days tinct. digitalis was given again, m. xx, q. 4 h., until 0.6 gm. of leaf had been taken when vomiting, slowing of pulse, and coupled rhythm returned.

Tables 1 and 2 present these case records more concisely.

Eleven patients, ranging in age from 15 to 65 years and all suffering from auricular fibrillation, developed either nausea alone, or nausea and vomiting, is a result of taking digitalis. The shortest time from the beginning of digitalis administration to the appearance of nausea or vomiting was about two days, in Case 7 the patient having taken 2 gm. of the leaf in this period. The longest interval was seven days, in Cases 1 and 8, in both of which it will be noticed that the effect of the drug on the heart was relatively less marked than the average. The average time elapsing from the beginning of digitalis treatment to the onset of nausea or vomiting was five days. The smallest dose causing nausea or vomiting in the first course of treatment was 1.6 gm., the largest 6.25 gm., and the average for the eleven cases was 3.08 gm., corresponding to about 7¾ drams of the tincture.

---

[*] To save space this paper has been abridged by the omission of case reports, except one typical case (Case 4), and the illustrations. The complete paper will appear in the Transactions of the Section and in the author's reprints.

[*] From the Laboratory of Pharmacology, Cornell University Medical College.

[*] Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

[1] Eggleston, Cary, and Hatcher, R. A.: The Emetic Action of the Digitalis Bodies, Jour. Pharm. and Exper. Therap., November, 1912; The Emetic Action of the Digitalis Bodies, The Journal A. M. A., Feb. 15, 1913, p. 499.

[2] I have to thank the several visiting physicians, Drs. William Gilman Thompson, Warren Coleman, F. S. Meara, Lewis A. Conner, and William R. Williams for the privilege of making these observations.

Five of the patients received a second course of digitalis from which nausea or vomiting also resulted, and in each case the total quantity of digitalis required to cause these symptoms was less in the second course than in the first. Except in Case 3, in which there was an interval of sixty days between courses, and possibly also in Case 2, in which the interval was twenty-four days, the smaller second course is attributable to the persistence of action of the drug from the former course.

Some of the patients had complained of nausea and vomiting when admitted to the hospital, and one or two vomited a few times within the first few hours, but in no case did these symptoms persist after the first twenty-four hours of treatment with digitalis, which in itself is evidence of an improvement in the heart action with a diminution of congestion resulting from absorption of the drug. Such an observation shows, further, that the digitalis given did not cause vomiting by irritation of the gastric mucosa, even in these cases in which this was rendered abnormally irritable through congestion.

1. The dose was reduced to dr. 2 after four days.
2. The single occurrence of a rate of 56 in the first series is probably attributable to the fact that the pulse was irregular and weak, and that not all beats were felt.
3. Three minims of fluidextract of digitalis preceded the administration of the tincture.
4. In Case 4 after the first vomiting the digitalis was continued in the same doses, but with the addition of tr. nux. vomica m. x. to each dose. This, however, had no effect on the vomiting, so both drugs were then stopped. In Case 6 the second course of digitalis was given along with m. x of tr. nux. vom., which, however, did not prevent the return of the vomiting.
5. In Case 6 atropin sulphate 3/100 grain subcutaneously caused the disappearance of the coupled rhythm and accelerated the pulse from 42 to 70 per minute. In Case 10, 3/100 grain of atropin sulphate subcutaneously caused very little increase in the pulse-rate—a rise from 27 per minute to 46 per minute.
6. Infusion of digitalis (1½ oz.) was given prior to the use of the tincture
7. As the patient was in a serious condition strophanthin 0.5 mg. was given before the use of digitalis was started.

* c-r.=coupled rhythm; cl. imp.=clinical improvement.

TABLE 2.—CASES OF CHRONIC CARDIAC VALVULAR DISEASE WITH REGULAR RHYTHM

Case	Digitalis	Am't Dig. at N. or V. Gm. of Leaf	Pulse at beginning of Digitalis	Nausea or Vomiting	Pulse at Time of N. or V.	Other Effects of Digitalis at Time of N. or V. with Reference to Action of Drug on Heart.

13	T.m. x t. i. d.	2.00	68	N.	58	Recurrent h-b. Clin. imp. See Note 1 below.
	T.m. xx q. 4 h.	0.60	64	V.	48	Recurrent h-b.
14	T.m. xv q. 4 h.	2.30	88	V.	75	Clinical improvement. See Note 2 below.
15	T.m. xv q. 4 h.	2.66	72—92	V.	60—72	Clinical improvement. See Note 2 below.

1. In both instances the administration of atropin removed the heart-block, but in neither did it cause more than a trifling acceleration of the pulse.
2. In Case 14 the course of tr. dig. was broken by 5 doses of ½ oz. each of infusion. In Case 15 the tincture was given for 8 doses, being then followed by the infusion in ½ oz. doses q. 4 h. for 8 doses.

Tincture of nux vomica has been said to prevent the vomiting resulting from digitalis if given along with it, but this was not the case with Patients 4 and 6 in this series.

In the four cases with regular rhythm, the signs of the action of the drug on the heart at the time of the nausea or vomiting were none the less definite, though, in general, they were not so striking as in the case of those patients whose hearts were in a state of fibrillation. This is in accordance with the almost universal observation that the rate and rhythm of the heart under the control of the normal pace-maker is less easily and less markedly affected than is the case when the normal pace-maker is not in control.

The average emetic dose in this series was 2.4 gm. (first course). The average time from the beginning of treatment to the appearance of nausea or emesis was seven days as compared with five in the previous series, the difference being due in great measure to the fact that less digitalis was given per day than in the first series. Cases 12 and 13 show "cumulation" of the drug, as regards both emetic and cardiac actions.

In none of these fifteen cases did the nausea or vomiting bear any constant time relation to the administration of the dose of digitalis, and in most cases nausea or vomiting persisted or recurred for some hours after the last dose had been given and the drug withdrawn.

To supplement my personal observations I have collected all of the cases reported in *Heart* from its first number to, and including, the latest issue at the time of writing (Volume IV, No. 2) in which sufficiently detailed accounts are available for me to determine the relation of the nausea or vomiting to the effect of the drug on the heart. A few of the cases reported by Cushny, Marris and Silberberg are omitted, being taken instead from the more detailed account given by Silberberg in his paper. No reported case which showed either nausea or vomiting has been omitted if the details given were at all adequate to the requirements. The cases, therefore, are not selected, except in so far as sufficiency of reported detail is concerned. These cases are given in Tables 3, 4 and 5, together with an indication of their exact source for reference.[4]

From Table 3 and notes, it is obvious that in every instance the development of nausea or vomiting was associated with definite evidence of the absorption of the digitalis and its action on the heart. The average amount (first course) causing these phenomena was 3.66 gm. of leaf (minimum 1.5 gm., maximum 8.5 gm.). As in my personal observations, the interval before the onset of nausea or emesis was several days, always more than two.

In Table 4 five instances of nausea or vomiting are recorded in which there was no certain evidence of the action of the drug on the heart. Four others (Cases 40 to 43) which were not "cardiac" cases also failed to show definite evidence of digitalis action on the heart when nausea or vomiting developed. It is remarkable that of so many patients with the normal heart-rhythm such a large proportion should have shown definite signs of the cardiac action of digitalis, when given in therapeutic doses. In this series the average amount taken before nausea or vomiting was caused was 3.34 gm. of leaf, and the interval was never less than two days.

* The first vomiting came on before noticeable slowing of the heart, but a note on the next day records clinical improvement, and slowing *soon appeared. In the second course the slowing was synchronous with the vomiting. A third course gave results exactly* similar to the second—slowing and coupled rhythm together with vomiting.

† Two additional courses of digitalis caused nausea in one and vomiting in the other, together with slowing.

‡ The slowing was not marked and lasted for one day only, but the clinical improvement was very definite.

§ Continuation of the digitalis caused a recurrence of nausea and the pulse slowed still further.

¶ Tincture of strophanthus was subsequently given to this patient (dose and interval not stated) and caused vomiting together with marked slowing of the pulse-rate.

DISCUSSION

Pharmacologic studies[1] show that in therapeutic doses the digitalis bodies produce nausea and vomiting by their direct action on the vomiting center in the medulla, and probably in no other way, for:

1. All true digitalis bodies are more actively emetic when administered intravenously than when given by mouth.

2. When emesis follows the oral administration of these bodies to cats it can be shown that emetic doses have been absorbed, and, on the other hand, when emesis does not result from the oral administration of many times the fatal vein dose, it can be shown that absorption has not taken place.

3. The phenomena characteristic of emesis follow the intravenous administration of the digitalis bodies to dogs after the removal of the gastro-intestinal tract.

As a result of these observations, and in the absence of any contrary evidence, we expressed the opinion that the emesis and nausea resulting from the clinical use of these drugs were due to their action on the vomiting center after absorption.

As evidence of the absorption of digitalis in man I chose its action on the heart. It was obvious that no two patients would respond with precisely similar indications of the cardiac action of the drug and, therefore, one or more of the following responses was believed to afford sufficient evidence of the action of the drug on the heart: (*a*) slowing of the pulse-rate definitely dependent on the use of the drug; (*b*) traceable alterations in the heart rhythm, such as heart-block (partial or complete), coupled rhythm, auricular fibrillation, ventricular extrasystoles, sinus arhythmia, or combinations of these; (*c*) clinical improvement, as indicated by diminution in, or disappearance of, cyanosis, dyspnea, orthopnea, venous congestion; decrease in the size of area of cardiac dulness; diuresis. It has been my practice throughout the analysis of the cases not to accept less than two of the phenomena in the third group as sufficient evidence of the action of the drug on the heart, and, therefore, of absorption of an effective quantity.

A further point in evidence of absorption, but one less constantly encountered through the circumstances of the case, is the presence of "cumulation" as shown by the need of a smaller amount of the drug in a second course of treatment to bring about an action on the heart.

---

[4] In the tables the initials refer to the names of the authors as follows: M.—Mackenzie: Heart, 1910-1911, ii, 273. W.—Windle: Heart, 1911-1912, iii, 1. A.—Agassiz: Heart, 1911-1912, iii, 353. L.—Lewis: Heart, 1912-1913, iv, 171. C., M., S.—Cushny, Marris and Silberberg: Heart, 1912-1913, iv, 33. S.—Silberberg: Tr. Roy. Soc. Med., 1911, Pharm. and Therap. Sect., p. 192.

In Tables 1 to 5, and the accompanying notes, I have collected and recorded 110 courses of treatment with one or other of the digitalis bodies resulting in nausea or vomiting.

All of the observations were most carefully made and I have subjected the cases taken from the literature to the same rigorous conditions of analysis as held for my own. The observations were made by no less than seven different men other than myself. They are summarized in Table 6.

Of 106 courses of digitalis treatment in cardiac disease resulting in the appearance of nausea or vomiting, 100, or 94.3 per cent., showed indisputable evidence of absorption of the drug prior to the onset of these symptoms. In fifty-five observations on cases with auricular fibrillation, nausea or vomiting was associated with the absorption of the drug in every instance. In fifty-one observations on cardiac cases with the normal rhythm, indisputable evidence of the absorption of the drug was available in forty-five instances, or 89.6 per cent. In four noncardiac cases there was no evidence of the action of digitalis on the heart, but it must be mentioned that each of these patients took an amount of the drug equivalent, at least, to the minimum taken by the others who did show evidence of action on the heart, before nausea or vomiting was induced. This is also true of the six instances in cardiac cases in which there was either no evidence, or in which this was insufficient, for the positive statement that absorption had occurred. It is therefore quite evident that one would be justified in concluding that even in these instances absorption had taken place before the nausea or vomiting developed. If this is granted, there is, then, but a single instance in the entire series of 110 observations in which there is any doubt that the nausea and vomiting resulted only after the absorption of a sufficient amount of the drug. This one possible exception is referred to in the second footnote under Table 4, and in view of the facts just brought forth it seems unlikely that this was due to local action of the digitalis on the alimentary mucosa.

These observations not only yield overwhelming evidence to show that nausea and emesis resulting from the clinical use of the digitalis bodies are dependent on the absorption of a sufficient amount of the drug, and, therefore, as in animals, on its central action, but they afford equally unequivocal evidence against the belief in the local irritant action of these bodies. The drug was given by mouth in amounts varying from 0.25 mg. (1/250 grain) of crystalline digitoxin (Nativelle's digitalin granules) up to 0.21 gm. (3⅓ grains) of digitalis in the form of infusion, and 0.24 gm. (3¾ grains) in the form of tincture (British Pharmacopeia) at a single dose without causing any nausea or gastric symptoms whatever in the entire series, with but a single exception, prior to absorption of a sufficient amount to cause cardiac effects, although the dose was repeated at intervals ranging from once in six to once in four hours. I have in addition given several single doses of a dram of the tincture (6 grains or 0.36 gm. of leaf) of digitalis to different patients and have never seen nausea or vomiting result

* The notes state that the patient felt better, but that there was not much improvement, and the table shows no slowing of the pulse. The second course of digitalis was followed by vomiting associated with indisputable evidence of digitalis action on the heart.

† This patient vomited on the second day, after 0.75 gm. of digitalis, but there is no note to guide me in forming a correct opinion of the cause of this vomiting; it is possible that it was due to the digitalis, but it is just as likely to have been the result of some other cause, such as the venous congestion so often present in cases of deficient heart action. In two other courses of digitalis (in addition to the one in the table) there was vomiting, and in one of these slowing was marked.

‡ The detailed record shows the pulse to have slowed from 72 to 80 to 57 to 60, though the notes state that there was no appreciable effect on the heart-rate.

§ The heart-block appeared in tracings taken on the day after the vomiting and cessation of digitalis.

¶ The notes state that the respiration had become easier.

‖ These phenomena were repeated after another course of digitalis (3 gm.).

** The notes state that after the first course the patient felt better than on any day since she had been in the hospital.

†† On the date of vomiting, "A pulse rate of 54 and one of 100 was noted . . . ."

‡‡ A second course (1 gm.) caused nausea but no effect on the heart rate.

directly from such large doses.[5] These observations controvert the statements that the digitalis bodies are irritant to the gastro-intestinal mucosa in therapeutic amounts. This agrees precisely with the experimental observations made by Dr. Hatcher and myself on this point. We also found that even the commonly incriminated fixed oil of digitalis, and digitonin, did not irritate the stomach or cause vomiting, except when the latter was given in enormous quantities, such as would be utterly impossible in the use of even the most impure galenical.

CONCLUSIONS

1. There is neither valid experimental nor clinical evidence that therapeutic doses of the digitalis bodies cause nausea or vomiting through local irritant action on the alimentary tract.

2. There is very strong evidence, both experimental and clinical, for the statement that the digitalis bodies do not cause vomiting or nausea by local irritation of the alimentary tract.

3. There is experimental evidence that the nausea and vomiting resulting from therapeutic quantities of these bodies are due solely to their direct action on the vomiting center and therefore result only after the absorption of a sufficient amount of the drug.

4. The clinical evidence brought forth in this paper is in agreement with all preceding experimental evidence to the effect that nausea and vomiting from therapeutic quantities of the digitalis bodies result from their absorption, and not from their local action.

5. The conclusion that the nausea and vomiting resulting from the therapeutic use of these bodies in man are due to their direct action on the vomiting center is a logical necessity.

I do not wish to imply that, in certain rare instances in patients whose reflex vomiting mechanisms are hypersusceptible, the administration of a dose or so of digitalis might not cause vomiting quite without the participation of any direct central action. We all know that a sip of milk or a drink of water is capable of provoking vomiting in some hypersensitive people. I do believe, however, that the emetic action of the digitalis bodies in man is central in practically all cases, and I believe that carefully conducted clinical observations will fully substantiate this statement.

DEDUCTION

From these conclusions I wish to make one deduction: Inasmuch as it has been shown that all true digitalis bodies produce nausea and vomiting by direct central action, it is fallacious and wholly irrational to seek to avoid these symptoms resulting from the oral administration of any given preparation by resort to another preparation or to another channel of administration. Such means have been resorted to frequently and often with a disappearance of the nausea or vomiting. When this has been the case the new preparation has been either weaker or less well absorbed, or the new channel has been one from which absorption has been less complete. Such observations do not in any way contradict the conclusions of this paper, but rather support them.

* In this case the heart-rate before the digitalis was given was only 30 per minute, and hence no slowing was to be expected as a result of treatment.

† The record states that there was marked retching (R) but no vomiting.

TABLE 6.—SUMMARY OF ALL OBSERVATIONS

Classification	Number of Instances Showing N. or V.	Number in Which There Was Positive Evidence of Action of Digitalis on Heart	Per cent. Showing Action on Heart
Auricular fibrillation	55	55	100
Cardiac disease with regular rhythm	51	45	89.6
Non-cardiac	4	0	0
Cardiac (total)	106	100	94.3
Total	110	100	90.9

ABSTRACT OF DISCUSSION

Dr. Clyde Brooks, Pittsburgh, Pa.: Dr. Schleiter and I carried out some experiments on the effect of digitalis on the blood-pressure of the unanesthetized animal. We incidentally observed that tincture of digitalis administered intravenously did cause vomiting. We agree with Eggleston and Hatcher that the emesis is a result of the action of the drug on the central vomiting mechanism.

Dr. Robert A. Hatcher, New York: The testimony of various clinical observers concerning strophanthus supports our own contentions regarding this drug. Fraser, in 1885, found that strophanthus caused fewer gastro-intestinal disturbances than digitalis, a fact which is explained, in part, by my own observations that strophanthus is not absorbed so readily as digitalis from the gastro-intestinal tract, but that strophanthus is actually less actively emetic than digitalis in proportion to the cardiac activity. Curiously, true digitalin, which has been supposed to be the least actively emetic, is in fact the most actively emetic of all of the digitalis bodies in proportion to its cardiac activity, the explanation of its seemingly slight emetic activity being that it has been used in extremely small doses.

---

[5] Since the reading of this paper I have given as much as 2 drams of the tincture (12 grains of leaf) at a single dose without causing either nausea or vomiting.

PHYSIOLOGY OF THE PYLORUS, PILLEUS VENTRICULI AND DUODENUM AS OBSERVED ROENTGENOGRAPHICALLY *

LEWIS GREGORY COLE, M.D.
Professor of Radiology, Cornell University Medical College
NEW YORK

Until 1892 the commonly accepted theory of gastric evacuation had been that offered by Richet and Rossbach, that the stomach contents were first thoroughly mixed with the gastric juices and, after three or four hours, passed rapidly into the duodenum. This conception was discredited by the results of independent investigations on dogs by Hirsch (1892) and Mering (1893), who substituted for it the theory of a rhythmically opening and closing pylorus, through which evacuation began immediately after ingestion. In 1898 Canno announced the discovery of a progressive peristalsis in the cat, and eleven years later Kaestle, Rieder and Rosenthal demonstrated a corresponding phenomenon in the human being.

My conception of the gastric motor phenomenon has been previously described,[1] and will therefore be referred to only in brief. Like the heart-action, gastric action takes place in cycles, marked by a systole and diastole or an alternating contraction and relaxation of all of the peristaltic waves (Figs. 1 to 4). A cycle exists during the time occupied by the formation and duration of each terminal wave. Accordingly the number of cycles required for the progress of an individual peristaltic contraction from its origin near the fundus to its termination at the pyloric sphincter is determined by the number of waves simultaneously exhibited in the stomach. The motor phenomenon is therefore said to be of the one, two, three (Figs. 1 to 4), four, five or six cycle type.

The important rôle played by the small intestine in gastric evacuation was recognized by physiologists thirty years ago; but the peculiar function and diagnostic significance of that region known as the first portion of the duodenum has not been fully comprehended heretofore. It has none of the characteristics of the descending and horizontal duodenum. On the contrary it corresponds so entirely in contour with the pars pylorica and has so many characteristics of the stomach that roentgenographically one is compelled to consider it a continuation of the stomach itself (Figs. 5 to 8). These points were fully described by me[2] in an article in which the term "pyloric cap" was first applied to the first portion of the duodenum. The word cap is more popular than scientific, however, and therefore, with the aid of Dr. Tower of the New York Museum of Natural History, I selected the latin term "pilleus ventriculi," or cap of the stomach.

Considering the active interest now being evinced in duodenal ulcer, as indicated by the recent communications of Moynihan, Codman, the Mayo brothers, Schwartz and Strauss, it may be appropriate more fully to state my reasons for referring to this region as gastric rather than duodenal. Embryologically it has long been recognized that the upper portion of the duodenum is stomach rather than intestine. Mayo[3] calls attention to the fact that "in the early state of fetal existence the duodenum above the common duct is part of the pyloric end of the stomach. Coming from the primitive foregut, it is associated with the stomach in its physiology and pathology, and it is not part of the small intestine, which comes from the midgut."

Anatomically the first portion of the duodenum differs materially from the descending or horizontal portions. Dwight[4] observes that "the first or ascending portion of the duodenum has a strikingly different appearance from the second and third portions, which present numerous, small, irregular folds, particularly on the posterior aspect."

Schwarz[5] calls attention to the dilatation of the pars superior duodeni as observed roentgenographically, and from anatomic and histologic studies notes the resemblance between it and the stomach. 1. The pars horizontalis superior has a smooth inner wall, presenting the delicate, striped longitudinal folds of the stomach lining. The ring-like folds characteristic of the upper part of the jejunum are not present, but appear first in the upper portion of the descending duodenum. 2. Together with the stomach it is attached to the liver by the gastroduodenal hepatic ligament. 3. Histologically it resembles the pars pylorica in that the pepsin glands of Brunner are found here in abundance.

Physiologically the contents of the cap are acid, like the chyme in the stomach.

Surgically 95 per cent. of the ulcers which occur beyond the pylorus are found in the first 1½ inches of the intestine, namely, the cap. They should therefore be described as postpyloric rather than as duodenal ulcers.

The first roentgenograms presenting the cap were exhibited by Henry Hulst in 1906 to illustrate his presidential address before the American Roentgen Ray Society.[6] Its roentgen shadow, however, so closely resembles the pars pylorica that Hulst interpreted this postpyloric region as the pyloric antrum. The dimensions of the cap, like those of the stomach, depend partly on its distention during different stages of digestion, different phases of the cycle and different stages of duodenal peristalsis (compare Figs. 1 and 2 with Figs. 3 and 4). The posture of the body also influences its size, shape and position. The roentgenographic appearance of the cap is of inestimable value in the recognition of gastroduodenal lesions. Variations resembling pathologic deformities are often seen in some of the plates of each series, but these can be readily recognized and definitely differentiated from organic changes. The small indentation frequently observed on either the right or left side of the cap may be due to pressure from the descending portion of the duodenum, the common bile-duct, or the vena porta (Fig. 6). Spasmodic contraction of the cap (Fig. 9) is often the result of iliac stasis, a Lane's kink, or a diseased appendix. Incomplete filling of the cap may be caused by overactive duodenal peristalsis (Figs. 10 and 11). This is more likely to occur in the early stage of digestion, when the pyloric sphincter is strongly contracted, than in the later stages when the sphincter is relaxed and the gastric peristalsis more efficient, even though less active (compare Figs. 12 and 13, and Figs. 15 and 16).

The function of the cap is that of a reservoir. It receives the acid chyme propelled through the pylorus during the systole of each cycle (Figs. 1, 2 and 8). During the early stage of digestion the chyme is rapidly withdrawn from the reservoir cap by a rather broad periodic peristaltic contraction (Figs. 7 and 10), which propels it through the duodenum, possibly caused by the alternating alkaline and acid reactions in this portion of the intestine. As digestion progresses the cap is more completely filled with the acid chyme, and, considering the presence of Brunner's glands, it is probable that the finishing touches of gastric digestion are received here by the small portion of chyme thus isolated from the bulk of food in the stomach.

The cap is separated from the pars pylorica by a space varying from ⅛ to ¼ inch, indicating the pyloric sphincter (Fig. 8). The importance of its roentgenographic appearance is second only to that of the cap in the diagnosis of lesions in this region. Both its gastric and duodenal surfaces should be smooth and clear-cut, and the lumen should be centrally located. The amount of contraction of the pyloric sphincter is clearly defined roentgenographically. As a rule, it is in proportion to the activity of the gastric peristalsis, that is, when the gastric peristalsis is feeble the contraction of the sphincter is weak (Fig. 13), and when the gastric peristalsis is strong, the sphincter is more tightly contracted (Fig. 12). Alteration in the balance between the contraction of the sphincter and the tone of the stomach is one of the functional disturbances of the pylorus which can be recognized roentgenographically. It causes either a retention of food or an unusually rapid evacuation of the stomach with dilatation of the cap, and sometimes dilatation of the duodenum and jejunum (Fig. 14). In the earlier stages of digestion, when the gastric peristalsis is active, the muscle of the pyloric sphincter contracts

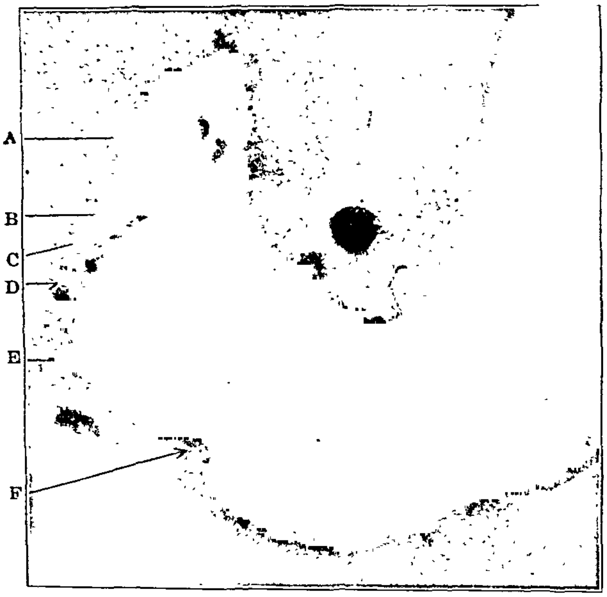

Figure 1.

Two phases of stage of diastole (same case as above). Note relaxation of peristaltic contractions.

therefore, duodenal receptivity controls the evacuation of the cap through duodenal peristalsis rather than the evacuation of the stomach through a pyloric reflex.

Whether the rapid withdrawal of chyme from the cap during the early stage of digestion (Figs. 12 and 15) results from its slight acidity or its fluidity or is demanded by the hungry intestine below is beyond my sphere to determine. Here is a fertile field for physiologic research. Personally I believe that the hungry intestine is an important factor, because, when the food reaches the ileum, the activity of the duodenal peristalsis is much diminished and consequently the cap retains more and the jejunum receives less than during the early stage of digestion.

The motor phenomena of the pylorus, pilleus ventriculi and duodenum herein described as observed roentgenographically, may be demonstrated in all human stomachs having a moderately active peristalsis. Whether or not the same is true of the lower animals I do not know. It may be that especial activities have been evolved by the erect posture of man, differing from the gastric motor phenomena in the lower animals.

103 Park Avenue.

ABSTRACT OF DISCUSSION

Dr. W. B. Cannon, Boston: The phenomena of systole and diastole of the stomach along with peristalsis I have observed in the dog, but I do not recall ever having observed them in the cat. In the cat the waves run along smoothly from their origin. The phenomenon of the cap I have never seen in the lower animals. As the food emerges from the stomach it is shot along the duodenum for some distance, but does not accumulate, in my experience, immediately beyond the pylorus. The phenomenon of the "cap" raises the question as to the control of the discharge from the stomach in man. In the lower animals, I believe that the evidence is pretty clear that the discharge is controlled by the acid reaction of the contents, and I should rather expect that that would be the explanation of the discharge in human beings. It would be interesting indeed to know what the effect of different foodstuffs would be on the rate of the discharge. The idea that the pylorus opens "periodically" in lower animals, is one that ought not, I think, to be allowed to prevail; at least, I am quite sure that that is not the way in which the pylorus opens in the cat and dog, if by "periodic" is meant at perfectly rhythmic intervals. As I tried to explain in a paper which I wrote in 1898, a wave coming along will discharge food through the pylorus, and then there may be no discharge for the next three waves, we will say, and the fourth wave will again discharge food through the pylorus and perhaps the next seven or eight waves may not discharge food. In other words, there is not a discharge in these animals with every wave or every fifth wave, or with anything like the rhythmicality which is observed in the peristalsis of the stomach itself.

Dr. A. J. Carlson, Chicago: The motion pictures were so confusing that I would hesitate to base any conclusion on them alone. I presume that the results with roentgenoscopy have been controlled by the fluoroscopic observations. There is no question but that Dr. Cannon's description of the action of the pylorus in cats and dogs is correct. My observation has been made on fifty or sixty animals and in every case the opening of the pylorus occurs as Dr. Cannon has described. Owing to the position of this upper end of the duodenum in man when in the upright position there may be a retention there and a tendency to dilatation; but I doubt Dr. Cole's "systole and diastole theory." It makes necessary an entirely different control of the pylorus in man than in the dog and the cat. I should like to ask for the authority for the statement that this portion of the duodenum secretes hydrochloric acid.

Dr. J. T. Case, Battle Creek, Mich.: From my experience with several thousand bismuth-meal examinations, I find I am not altogether in accord with the views expressed. Dr. Cole has made his studies roentgenographically, involving the production of numerous roentgenograms. The moving-picture films have been pieced together, so to speak, and they are not true cinematograph reproductions, and some of the happenings apparently shown by the films are, I believe, artifacts.

My observations have been made with the fluoroscope and are based on roentgenographic studies of the stomach in several thousand cases. In my opinion, a sort of systole and diastole does occur, but not in the normal stomach. I have seen the phenomenon described by Dr. Cole, but my impression has always been that the cases in which it occurred have been those of pyloric obstruction and that periodically the stomach becomes fatigued. During the periods of fatigue, peristaltic waves are not so deep as they are at other times. When the stomach becomes rested, as it were, the waves become deeper. If it were possible to make a cinematographic film extending over a sufficient period of time, taking every wave of the stomach, I believe we should find, in certain pathologic stomachs, this phenomenon described by him as systole and diastole, and yet we should see that between the two phases there would be a considerable period of time. On the other hand, Cannon's observations as regards the control of the pylorus in animals have been absolutely confirmed in my observations on man. In fluoroscopic observations, I have repeatedly seen the behavior of the pylorus as described by Cannon, the opening of the pylorus occurring irregularly. After three or four waves have reached the pylorus, one may see the pylorus open and food pass through into the duodenum. Then again ten or twelve waves may reach the pylorus before it opens again. I have not been able to observe any rhythm or regularity as to the opening of the pylorus in man.

Dr. W. B. Cannon, Boston: May I ask Dr. Case to describe his experience with the fluoroscope as applied to the cap? Is the appearance of the cap uniform?

Dr. J. T. Case, Battle Creek, Mich.: It has been hard for me to make up my mind with reference to that because so many of my cases have been pathologic and I have consequently hesitated to draw conclusions. From my observations on normal people, limited to forty or fifty persons, I must say that I have seen peristaltic waves empty the duodenal bulb completely at times. In working with the fluoroscope in favorable cases, one may see very well the succession of waves reaching the pylorus, with occasionally an opening of the pylorus and the passage of bismuth on into the duodenum. My experience with fluoroscopic observations of the stomach in man confirms the conclusions of Cannon based on animal experimentation. My conception of the function of the duodenal bulb is that it acts more or less as an equalizer, receiving the food from the pylorus and serving it into the duodenum in appropriate quantities. Holzknecht, years ago, called attention to the fact that the first part of the duodenum rarely undergoes peristaltic contraction.

Dr. E. W. Caldwell, New York: From fluoroscopic examinations which I have made I cannot agree with Dr. Cole that the shape of the so-called pyloric cap is peculiar to any individual. With the patient in different positions, and with different degrees and direction of pressure we can obtain almost any style of pyloric cap in the average person. Whenever we see the so-called pyloric cap triangular we may conclude that it is because the duodenum is deformed by pressure. I am, therefore, inclined to regard the triangular cap as an artifact.

Dr. Lewis Gregory Cole, New York: My description of the evacuation of the cap corresponds so accurately with Dr. Cannon's description of the evacuation of the antrum, that Cannon, like Hulst, may have mistaken the cap for the antrum, and the occasional peristaltic contractions, which he describes as discharging the chyme through the pylorus, are what I mean by the broad, peristaltic contractions, which begin in the top of the cap and propel the chyme through the duodenum. This broad, propulsive peristalsis of the duo denum may be controlled by an alternating acid and alkaline reaction in the descending duodenum. The relative value of fluoroscopy and roentgenoscopy is not a question to discuss before this section; but when the cap is shown in every one of forty plates, how can you doubt its presence, even though it is seen only occasionally on the fluoroscopic screen. Astronomic observations are based, not on ocular, but on photographic records. Photograph a man walking, and the snapshot will picture his feet in an incredible position. Similarly, I do not understand how you can discredit the definite evidence of the cap afforded by the permanent records of serial radiography. The photographs are assembled in the order of the progression of the peristalsis, and double exposures, made about one-half second apart on the same plate, provide the key which locks them together. Dr. Case says that he has not observed the systole and diastole fluoroscopically. By making a series of roentgenograms and comparing the extremes of systole and diastole, he will find a motor phenomenon not accounted for by the progression of peristalsis, and not readily recognized fluoroscopically. Furthermore, it is a phenomenon different from the periods of repose that occasionally occur during gastric digestion. The systole and diastole occur once during each cycle, which corresponds in time with the formation and duration of an antrum. The antrum exists for about seven seconds, I believe. The length of the cycle varies in different people, and I should rather not state the average time. Photographs made about four seconds apart show the extremes of systole and diastole. The peristaltic wave persists about twenty seconds from its origin at the fundus to its termination at the pylorus, not twenty seconds for its progression along the last two inches of the stomach. The systole and diastole correspond in time with the wave. I have my own opinion of the average length of time, but do not care to name it. I do say, however, that it corresponds with the formation and duration of each antrum or cycle.

UNIQUE WRIST INJURY

RECURRENT ANTERIOR DISLOCATION OF ULNA *

A. C. YODER, A.B., M.D.
GOSHEN, IND.

History.—Mrs. R., aged 36, Feb. 28, 1910, fell down-stairs and in some way hurt her left wrist. She immediately came to my office three blocks distant. Walking into the consultation room she held out her forearm in medium pronation, the hand and fingers slightly flexed. The patient thinks now that the hand was somewhat drawn to the ulnar side. I noticed an abnormal protuberance on the dorsum of wrist and made a hasty (before examination) diagnosis of Colles' fracture.

Examination and Treatment.—I examined the wrist and soon discovered that there was not a Colles' fracture; nor could I make out any fracture, except possibly one of the ulnar styloid. It was discovered that the ulna was dislocated forward and that it was easily reduced, but that when the pressure which was needed to reduce it was released, dislocation recurred. Motion in all directions was somewhat limited on account of pain. The deformity on the back of the wrist could not be reduced by manipulation or by pressure. By means of adhesive strips and an anterior splint the dislocation of the ulna was maintained. Rest of the part was advised for several weeks. In the meantime the splint was readjusted several times, but finally abandoned. At no time did the ulna show any tendency to remain in its normal place except when it was held there by some retaining force. The patient was finally advised to wear a wristlet and to use her wrist and hand as much as she could. A roentgenogram made March 30, 1910, a month after injury, did not show any fracture. In June, 1911, more than a year later, the patient returned, complaining of pain and weakness in her wrist. Two roentgenograms, one dorsal and one palmar, were taken. These pictures showed no fractures or any marked or complete dislocation, except that of the ulna. The patient was again advised to wear a wristlet. Motion was practically normal. The patient did not wear the wristlet long, but soon used her hand as much as ever.

Present Condition.—At present the wrist has practically normal motion, except that the patient has some hyperextension and somewhat limited flexion. It is nearly as strong as her right wrist. The patient does all kinds of heavy housework, using the left wrist without a support. She has no pain in the wrist. The deformity on the back of the hand persists. The inferior end of the ulna projects anteriorly *when the hand is in supination.* It is freely movable and is easily replaced; in fact, it reduces itself when the hand is pronated. It can be felt slipping back into the sigmoid cavity of the radius as the hand passes from supination to pronation. I cannot make out the triangular fibrocartilage, but it evidently must be ruptured, judging from the abnormally free range of motion of the end of the ulna and the ease with which it slips back into place. We may safely infer, in addition, that the anterior radio-ulnar ligament is ruptured. The dislocation of the ulna is clearly shown in the roentgenogram of this wrist (made by Dr. Lemon) in lateral view. This picture shows the ulna protruding far to the palmar side of the wrist.

We must yet account for the deformity on the back of the wrist. Here we find ourselves on debatable ground. Through the kindness of Drs. Lemon and Haywood I have had several roentgenograms of this wrist for study and examination and have freely consulted their opinions as to their interpretation of the plates. My present conclusion is that there is a slight backward dislocation of the radiocarpal joint, and that the carpals, though none of them are dislocated, are crowded together, and some of them more or less rotated on their axes, or possibly even slightly dislocated. As to the first part of my conclusion, subluxation backward of the radiocarpal joint, the fact that the deformity is on the back of the hand speaks for backward rather than forward dislocation. Other evidences of backward displacement are the diminutive size of the hypothenar eminence and the fact that the whole wrist and hand lie on a higher or more dorsal plane than normal, carrying with them the ridge and tubercle of the scaphoid and trapezium, so that they lie deeper in the wrist than normal. However, there is not complete luxation backward, first, because motion never was limited enough for that; secondly, because deformity was not great enough, and thirdly, because the roentgenograms do not show complete luxation.

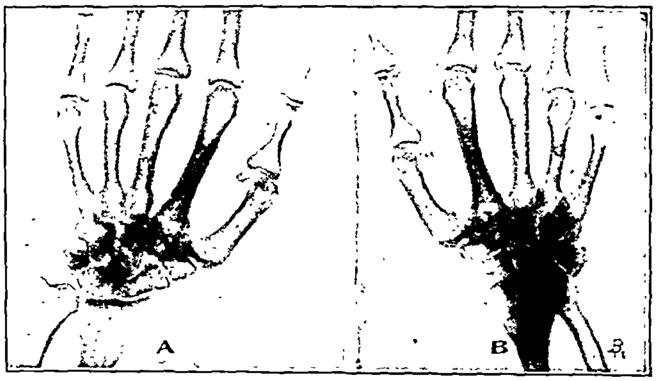

Fig. 1.—*A*, normal wrist (right); *B*, injured wrist (left). Shows crowding together of carpal bones, subluxation of radiocarpal joint and overriding of semilunar and os magnum.

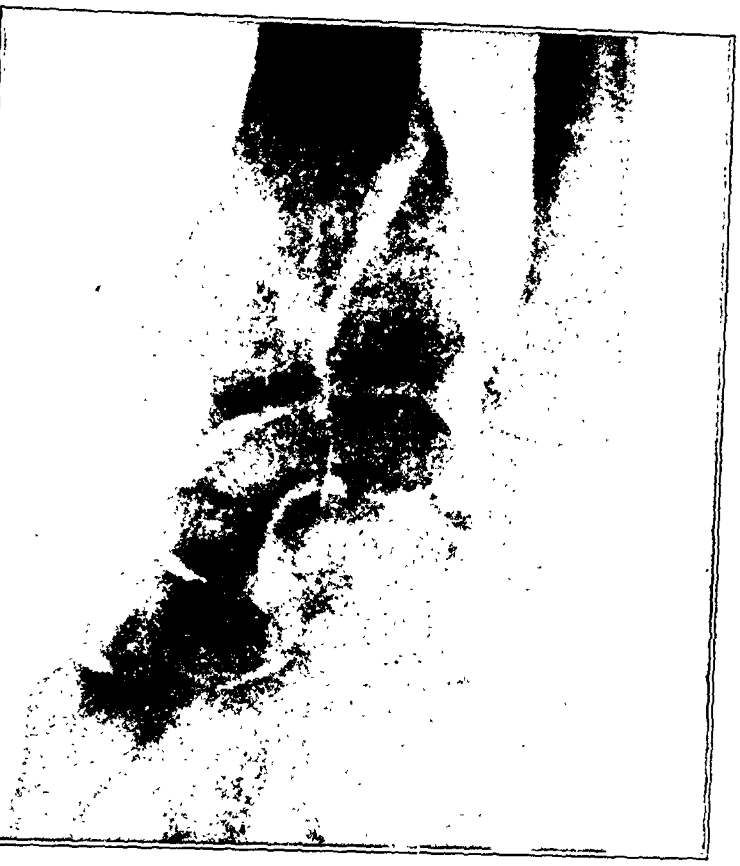
LONGITUDINAL FRACTURE OF THE LOWER END OF THE RADIUS TOWARD THE ULNAR SURFACE

James C. Wilhoit, M.D., Manhattan, Kan.

Longitudinal fractures of the lower end of the radius are exceedingly rare. Cotton[1] speaks of only three specimens. Parrish[2] and Bendell[3] probably have the only roentgenographic illustration of the lesion. So far as I can learn, this case is the only longitudinal fracture of the radius that split toward the ulnar surface.



Longitudinal fracture of lower end of radius.

J. H. G., farmer aged 38, May 3, 1913, was boxing hats; his antagonist caught him by the fingers of his right hand and in jerking to free himself he felt something in his wrist snap. He consulted me the day of the injury and on roentgenoscopy the fracture was located.

Gentleness in Surgery.—The fact that some operators produce little constitutional disturbance, little shock, by the performance of an operation which at the hands of another causes very serious collapse, is not due to differences in the patient, in the anesthetist, in the method, or in anything else but the surgeon himself. There are surgeons who operate on the "canine" principle of savage attack, and the biting and tearing of tissues are terrible to witness. These are they who operate with one eye on the clock, and who judge the beauty of any procedure by the fewness of the minutes which it has taken to complete. There are other surgeons who believe in the "light hand," who use the utmost gentleness, and who deal lovingly with every tissue that they touch. The former type of operator is described by Crile as "carnivorous;" the latter type is nowhere better exhibited than in his own work. The scalpel is, indeed, an instrument of most precious use—in some hands a royal scepter; in others but a rude mattock. The perfect surgeon must have the "heart of a lion and the hand of a lady;" never the claws of a lion and the heart of a sheep.—Sir Berkeley Moynihan, Address in Surgery, Brit. Med. Assn., 1913.

A FATAL CASE OF COCCIDIOIDAL GRANULOMA

Philip King Brown, M.D., San Francisco

History.—The patient was a Yaqui Indian, aged 30, speaking no English (history obtained through interpreter). He worked at McKittrick, San Joaquin Valley, California, with construction gang. He knew nothing of his family history. He said that he had never been sick before and denied venereal diseases.

Present Trouble.—July 25, 1911: Patient said that he had been sick for ten days. He felt warm and had pains all over him, in shoulders, hips and all joints. He had coughed for several months and had had some pains in the lungs. A couple of weeks after admittance, patient said that he had no pains anywhere, no chills and no sore throat, but that he had perspired freely day and night.

Physical Examination.—There was no evidence of a lesion anywhere. The heart-tones were clear and strong; there was no cough; there were no signs in the lungs of any trouble. The pain in the joints of which he complained was not bad, and there was no evidence of swelling or tenderness. Even the pain in the joints disappeared without medication and did not return. The urethra and prostate presented no sign of trouble. The tonsils were slightly large but not inflamed. Widal and Moro reactions were negative. Blood-culture, urine and stools were negative. The blood-count was 24,650 at time of entrance, but three weeks later was normal.

Treatment and Course.—The progress of the disease was without incident except for the fever and failure to determine the nature of the infection. At the end of two weeks, because of negative findings, a mixed vaccine was used on the patient, pneumococci and streptococci predominating. There was no effect from this after two weeks and vaccine treatment was discontinued. The pulse was slow and the temperature ranged 3 or 4 degrees daily and was very irregular, ranging from 95.6 to 104 F., and going below normal several times.

The patient grew gradually weaker, râles developed in the lungs and he died fifty days after entering the hospital.

Laboratory Reports.—July 26, 1911: Urine: dark yellow; specific gravity, 1.015; reaction acid; sugar negative; albumin negative. Microscopic examination showed amorphous urates and a few finely granulated casts. Diazo-reaction negative. Widal negative.

Aug. 3, 1911: Widal, negative; blood-culture, negative. Differential blood-count: polynuclears, 76.5 per cent.; eosinophils, 4.5 per cent.; large lymphocytes, 1 per cent.; small lymphocytes, 18 per cent.

Aug. 4, 1911: Moro reaction negative.

Aug. 11, 1911: Sputum: elastic tissue, none; bacilli of tuberculosis, negative; diplococci, some; streptococci, many. Several days later sputum examinations showed absence of tubercle bacilli but presence of many diplococci and streptococci.

Feces: No pus, mucus or ocult blood; no ova or parasites.

July 27, 1911: White blood-cells, 24,560.

Aug. 15, 1911: White blood-cells, 9,000.

Sept. 11, 1911: White blood-cells, 11,150; blood-culture, negative; bacteriologic examination of catheterized specimen of urine, negative; palpation of prostate, negative.

Necropsy.—By Dr. W. T. Cummins. Typical lesions of miliary tuberculosis in lungs with fewer lesions in the other organs. The primary focus was the lumbar lymph-nodes which were soft and caseous, fluid pus showing in certain of them. It was not until sections were made of these lymph-nodes and the lung that it was discovered that the lesions were due to the coccidioidal organisms. There were no ulcerations in the intestines.

Characteristics of the Preceding Case.—The initial lesions were in the lumbar lymph-nodes, whereas in about 70 per cent. of the cases the lesions were primarily in the lungs. There were no skin lesions, which are present in at least one-third of the cases. Blood-cultures were tried on three occasions and were negative; in no previous case, so far as I know, had blood-cultures been tried. The duration of the case could not have exceeded two months from the onset of the symptoms. The only other case as acute, in which the initial lesions were also in the intestinal tract is Case 15, of a duration of two and a half months.[1]

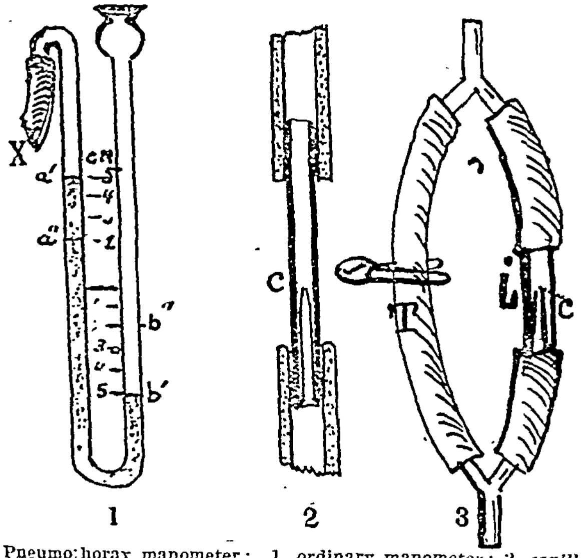
THE PNEUMOTHORAX MANOMETER

Edward von Adelung, M.D., Oakland, Cal.

I have been surprised to note that while all physicians who employ artificial pneumothorax agree on the great importance of being closely guided by the manometer readings, they are reading their manometers in different ways. As in many other instances in which the records of one man must be compared with those of others, it is of crucial importance that a uniform method of recording be agreed on.

The commonly used manometer is constructed as depicted, Figure 1, being simply a U glass tube filled to zero with a fluid, water. Thoracic pressures are transmitted through a tube, *x*, and depress or "suck up" the fluid. If the pressure varies, as during breathing, of course the columns will oscillate.

For example, the left column (Fig. 1), under negative pressure, oscillates from a′ to a″, and simultaneously the right oscillates from b′ to b″. During breathing they are in constant motion. Now the question answered so variously is, How should the manometer be read? Should one read in this case negative pressure 5, the figure to which the left column rises; 2, the lowest mark above zero that it reaches; 10, the *difference* between the tops of the two columns when at their maximum, or 4, the difference between them when they are at their minimum? Or, as some have suggested, should one read the averages: half the difference of the maxima or 5, or half the difference of the minima, or 2? Or should one read half of the oscillation between the maximum and minimum on one side of the manometer, in this case 3.5? Or finally, should this figure be doubled, making the reading 7? Such is the confusion of possibilities that present themselves to some minds.



Pneumothorax manometer: 1, ordinary manometer; 2, capillary link; 3, tube leading to manometer.

Of course there can be but one correct reading. Physics has long ago made clear that the pressure is measured by the column of fluid supported. Now the column supported is that portion of the longer column above the top of the shorter. The correct maximum reading in the given example is therefore negative 10, while the correct minimum reading is negative 4; but under these conditions some might read maxima and others minima, so we still have something to agree on. *It is suggested that the mean pressures be recorded.* In this case the mean pressure is negative 7.

I wish now to call attention to an attachment for the manometer which I discovered, by means of which the mean pressure can be read directly, a means of practically obliterating the oscillations, thus giving a positive-reading manometer for mean pressures. If this attachment were generally adopted differences in readings would vanish. The attachment is inexpensive, easily constructed, and applicable to any manometer. It is shown in Figure 2.

A capillary tube is fixed in a heavier tube (for protection) so that the pressure must pass through the small opening, *c*. This device is placed in one limb of the divided tube that leads to the manometer, as shown in Figure 3. When the rubber limb, *T*, is pinched off, forcing all pressures to reach the manometer through the link *L*, positive mean pressures will record with practically no oscillations; but the oscillations are necessary to prove the position of the needle. If tube *T* is left open oscillations occur as usual. Thus both uses of the manometer are readily available.

New and Nonofficial Remedies

The following additional article has been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Its acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on investigation made by or under the direction of the Council. Criticisms and corrections are asked for to aid in the revision of the matter before publication in the book "New and Nonofficial Remedies."

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that, so far as known, it complies with the rules adopted by the Council.

W. A. Puckner, Secretary.

BACILLUS OF BORDET-GENGOU VACCINE.

Sophian-Hall-Alexander Laboratories, Kansas City, Mo.

Whooping-Cough Vaccine (Bordet-Gengou Bacillus).—This vaccine is prepared from the Bordet-Gengou bacillus derived from a case of whooping-cough. Marketed in ampoules containing respectively 100 million, 350 million and 500 million killed Bordet-Gengou bacilli.

Therapeutics

BRASS-FOUNDERS' OR ZINC AGUE

This not infrequent and often unrecognized condition has been carefully investigated by Dr. Emery R. Hayhurst of Chicago.[1] Men who are exposed to the fumes of molten metals are more or less likely to become poisoned. With lead and mercury this has long been recognized. Perhaps there is no poisoning from pure molten iron or copper, but some one or more elements in brass, bronze, German silver, etc., may cause a peculiar condition termed "brass-founders' ague," and Hayhurst's investigations have shown that the more the fumes are inhaled, the more likely is this ague to occur; the more confined the room the more likely is it to develop. This is noticeable from the greater number of cases of poisoning in the winter than in the summer months when the windows and doors are open, and the weaker an individual, the more liable is he to have it.

Brass, it may be remembered, is composed of copper and zinc. The zinc often predominates, as it is the cheaper of the two metals. Bronze is a mixture of copper and tin.

---

[1] The following reviews of the cases may be found: Ophüls: Jour. Exper. Med., vi. Brown, P. K.: California State Jour. Med., December, 1906, p. 324. Brown, Philip King: Coccidioidal Granuloma, The Journal A. M. A., March 2, 1907, p. 743.

[1] Hayhurst, Emery R.: Am. Jour. Med. Sc., May, 1913, p. 723

While those who inhale the fumes of these metals when molten are most likely to be poisoned, those who are subjected to the dust from polishing or handling them (especially when the metals have become oxidized or carbonized) are also likely to have poisoning, although perhaps not so severe. They may have gastric disturbances, irritation and inflammation of the gums, and perhaps some forms of eczema.

The most important symptom of brass-founders' ague is the chill, with more or less fever and then sweating. With some persons this chill may occur shortly after inhaling the fumes, while others may withstand such inhalations until the latter part of the day, or may regularly be tolerant to a certain number of inhalations a day; but even in cases in which such tolerance is found, the person may have a chill if these fumes are repeated often during the day.

Besides the symptoms already mentioned, the mouth and throat are dry, there is more or less dry cough, a feeling of tightness in the chest, a metallic taste in the mouth and loss of appetite; nausea and vomiting may or may not occur; headache is generally present and sometimes severe backache and leg pains. With more or less lengthy prodromes a chill generally develops, and the patient may be chilly for from one to three hours. He is not readily warmed, even with blankets and hot-water bags, although hot drinks are a comfort to him. The pulse-rate is generally greatly increased. There is not always a rise of temperature before the crisis and the development of perspiration. With the perspiration comes prostration, weariness and drowsiness, and the patient sleeps. The attack may last, says Hayhurst, from five to twenty hours. When the patient recovers from the attack, which is more or less like a malarial chill and fever, he is pretty well, except that he may feel somewhat weary and may not have his usual appetite. Hayhurst says that the urine invariably shows albumin and casts after a severe chill. This soon clears up. No changes in the blood have been noted.

These chills are more likely to occur in the latter part of the afternoon, in other words, after more or less repeated or prolonged exposure to the fumes or dust of the metals; they may not occur, however, until the cool of the evening when the chilling seems to precipitate the ague.

Hayhurst's investigations seem to show that about 70 or 80 per cent. only of the workmen in these occupations are susceptible to the poison and experience the chills; hence, there must be some natural immunity. A tolerance also occurs in from 70 to 75 per cent. of the men who work steadily at the trade. The other 25 per cent. are poisoned more or less regularly, but rarely sufficiently to cause a change of occupation. Weak and anemic persons and women are more susceptible to the poisoning than the stronger men.

Investigations have shown that men in these occupations are more or less addicted to alcohol. This is largely owing to the belief that whisky especially is an antidote against this form of poisoning. Investigations have also shown that these men do not live so long as men in many other occupations, and the mortality from pulmonary tuberculosis is much greater than in most occupations.

Although it has not been definitely shown that it is the zinc which causes this kind of poisoning, it is quite probable that zinc is the metal.

Since treatment in these cases is not satisfactory, no specific treatment having been discovered, prevention is of more than usual importance. It is self-evident that in the manufacture and the handling of these metals and combinations of metals, factories and furnaces should be so equipped that the dust will not be inhaled, and the fumes should be sucked up the chimneys by fans and blowers so that it will be impossible for the workmen to inhale them. While sponges and various respirators have been used over the nostrils and mouth, resort to such measures should be necessary only in individual instances. Women and boys should probably not be employed in these industries; their general health should certainly be considered and anemic persons and those with a tendency to tuberculosis should be refused acceptance as employees in factories of this kind. Much on the plan of those who handle lead, frequent baths should be taken, the hands should be thoroughly washed before eating, and the workmen should not eat in the foundries.

The only symptomatic treatment advisable seems to be hot drinks, sometimes emetics and the administration of hot milk. Of course, if there is severe pain, a hypodermic of morphin must of necessity stop it, and theoretically would be good treatment. More or less all these patients probably need iron and bitter tonics.

While no distinct pathologic condition is known to follow these acute poisonings, repetitions of the poisoning or continued exposure to the cause, whether dust or fumes, sooner or later allows respiratory, urinary, or perhaps nervous disturbances to develop. Instances of neuritis have been known to follow such poisoning.

LEAD-POISONING

In communities in which there are industrial plants handling lead, poisoning from this source is frequent. It has been shown that the most poisonous or the most soluble forms of lead are not necessarily the most likely to cause accidental poisoning. Those that most readily form dust seem to be most harmful, the more the dust is abolished, therefore, in all forms of lead factories and lead industries, the less the poisoning. There is no question, of course, of the danger of lead fumes from molten lead.

The subject of industrial lead-poisoning has been carefully investigated by Dr. Alice Hamilton[2] of Chicago. She came to the conclusion that the most poisonous of the lead salts is probably the suboxid which forms on the surface of melted lead, is given off in fumes at high temperatures and also rubs off on the hands of the lead-workers; it is this salt that causes poisoning in smelters, molders, type-setters, plumbers and others. The other forms most likely to cause poisoning are litharge or oxid of lead, and then the higher oxids of lead, as red lead, and the carbonate of lead, or white lead. Those who clean or scrape off lead paint, and also painters, are likely to have poisoning from white lead. Lead-poisoning occurs frequently in factories in which men work in white lead, and in oxid of lead or red lead, and Dr. Hamilton finds that those who work in red lead are poisoned sooner than those who work in white lead.

She believes that a weak sulphuric acid lemonade, which workmen were urged to drink, is not a protective against lead-poisoning. It has been proved that most forms of lead will be so acted on by the gastric juice during digestion that some lead will be absorbed. The only harmless lead seems to be the sulphid of lead. A recent article of Drs. Carlson and Woelfel[3] reports the results of a special investigation as to the solubility and absorption of the different kinds of lead. This investigation was made at the request of Dr. Alice Hamilton.

[3] Carlson, A. J., and Woelfel, A.: The Solubility of Lead Salts in Human Gastric Juice and Its Bearing on the Hygiene of the Lead Industries, The Journal A. M. A., July 19, 1913, p. 181.

The amount of lead necessary to cause poisoning varies greatly, probably according to idiosyncrasy, some persons being susceptible, others being tolerant. Some artisans, therefore, may work in lead for years without evidence of poisoning, while others can work but a few weeks before poisoning is apparent. *Investigations* in some of our factories, Dr. Hamilton says, showed that from 25 to 35 per cent. of the employees had some form of lead-poisoning. Negroes seem more susceptible to lead than white men, and women are probably more susceptible than men. Fatigue, improper housing and insufficient food all render the individual more susceptible to lead-poisoning and its anemia, as we would logically conclude. Those who drink much alcohol are more susceptible to the poisoning, and the tendency to drink beer or whisky in order to remove the sickish, disagreeable, sweet taste from the mouth due to the lead salts that are inhaled or swallowed is great with men in these employments. Women, on the other hand, drink a good deal of tea, or crave sour things, to overcome this disagreeable taste.

It has not been shown that lead is positively absorbed from the skin, or that much is absorbed when inhaled into the lungs; probably most of the poisoning is caused by lead being swallowed into the stomach.

The diagnosis of chronic lead-poisoning is sometimes difficult, and for that reason every one should be questioned as to his possible exposure to lead, after other more tangible causes are excluded, if he loses appetite, is pale or anemic, is constipated and suffers from indigestion. These are all prodromal symptoms. The blue line on the gums may or may not be present. If the teeth and mouth are properly cared for the blue line is probably not often found. "The basophilic granulation of the red cells," which was thought at one time to be diagnostic of chronic lead-poisoning, has been shown not to be pathognomonic. Lead may or may not be found in the urine of patients who show other signs of lead-poisoning; therefore its absence will not exclude lead-poisoning. It has been suggested, in cases in which the patient is working in lead and poisoning is suspected, that a soluble sulphid be rubbed on the skin, on the theory that lead is excreted through the skin, and that if a black precipitate is formed, it will show that there is lead in the tissues.

Dr. Hamilton concludes that, although one attack of acute plumbism is not serious and may leave no diseased condition, one attack does predispose to another, and that probably a man who has had one attack of acute colic, for instance, or of wrist-drop, certainly should be ordered to stop working in lead, and that the employer should refuse him employment. The later pathology of chronic lead-poisoning becomes that of cardiovascular-renal disease on the one hand, or progressive anemia, weakened muscles, especially the extensors, tremor and emaciation.

In this anemia nucleated red corpuscles are almost always found, even if the anemia is not profound.

Lead colic may occur suddenly, or after protracted constipation, with or without gastro-intestinal pains, During the paroxysm the patient generally vomits, the pulse is slowed and the blood-pressure is generally raised. Nothing will stop this kind of pain but large doses of morphin, used in combination with atropin. Hot fomentations to the abdomen should be used, or better, if the patient is able, a hot bath should be taken. As soon as the pain is less severe the patient should receive a saline cathartic, and best perhaps Rochelle salt, as, in spite of the usual innocuousness of magnesium sulphate, it should not be forgotten that, occasionally, if magnesium sulphate does not cause purging and is absorbed, it can cause nervous depression not dissimilar to that which may occur from lead.

The after-treatment of lead-poisoning of this nature, or if chronic lead-poisoning is diagnosed without lead colic occurring, is a daily morning dose of *Rochelle salt* or something similar and the administration of small doses of sodium iodid. The dose of iodid should, as a rule, be small, not more than 0.20 gm. (3 grains) three times a day, after meals, as large doses may cause more lead in the system to become soluble than is desired, and more acute symptoms of lead-poisoning to occur. Anything that builds up the nutrition is also good after-treatment for chronic lead-poisoning; for example, the administration of small doses of iron, and the prevention of high blood-pressure and a possible beginning cardiovascular-renal disease.

If lead palsy, which in its most frequent form is wrist-drop, is present, the tonic treatment mentioned before should be carried out with the addition of strychnin and the use of electricity and massage.

Acute cerebral symptoms not infrequently occur. These symptoms may be a delirium, convulsions, epileptiform in character, or more or less coma. Occasionally hallucinations and insanity are caused by the action of lead on the brain. These conditions are all exceedingly serious. While wrist-drop is generally curable, more profound paralysis of the arms and legs is much more serious.

Prevention, of course, should be considered by every employer and should be understood by every employee who has anything to do with industries that make or handle lead. The prevention of lead-poisoning is much the same as previously described in the prevention of zinc ague, and a patient who has once been poisoned by lead should either leave his occupation or should inaugurate such means of prevention of future poisoning as are efficient. Personal cleanliness is one of the greatest factors in the prevention of lead-poisoning.

The Bureau of Labor[4] at Washington has issued a bulletin which describes the causes and prevention of lead-poisoning both in Europe and this country, representing the investigations of Oliver in Europe and of Alice Hamilton and John Andrews in this country.

Infection of Swimming-Pools.—Most modern swimming-pools have certain provisions which aim to prevent the contamination of the water. At many of the swimming-pools, the walks are so constructed that any water splashed on them drains away from the pool; expectoration in the pool is prohibited and nude bathing for men is the general rule. At many places each bather is required to take a preliminary bath before entering the water, but unless a conscientious attendant is constantly on duty this preliminary bath may be very superficial with many of the bathers. Medical examination of the persons using the pool, is required in some cases, but such examinations are usually made at such infrequent intervals as to provide only a small measure of safety from infection. Of the thirty-five swimming-pools reported by Mannheimer, at only twenty-three medical examination was made before a person was permitted to use the pool, and with very few exceptions no subsequent medical examination was made. At only eleven of these pools was there any inspection of those *entering*, and at only one was every one required to pass through the shower-room on the way to the pool.—Clark and Gage in *Bull. Mass. State Board Health.*

THE SIGNIFICANCE OF FORMIC ACID IN THE URINE

It would work a great step in advance in our understanding of the chemical processes of the organism and unquestionably render much assistance in the interpretation of the various perversions of the nutritive functions if all the important steps in the life-processes of the body were adequately known. The discovery and recognition of these intermediate stages is rendered peculiarly difficult owing to the fact that many of the products which unquestionably arise as transition fragments in the destruction of larger nutrient molecules escape detection because they are themselves speedily further altered by oxidation, reduction or other chemical reactions, until step by step the end-products are reached without the disclosure of any of the transitory stages. Only when some of these evanescent intermediate compounds crop out by accident, as it were, are we made to realize that they are incidents in the story of degradative changes in living organisms.

The present research in metabolism is particularly concerned with the appreciation of such intermediary products and the processes by which they arise. Accordingly one reads more frequently than formerly of lactic acid and the various ketone compounds, acetone, diacetic acid, beta-oxybutyric acid, of hydroxyacids and ketonic acids all brought into growing prominence by the newer point of view which is being presented. This phase of physiology, full of the promise of revelations in respect to the detailed chemical workings of the body, is still in an early state of development. The novelties of the subject are still brought to our notice in isolated instances. Formic acid, for example, has lately commanded attention as a possible transition product. Its comparatively simple chemical structure, H.COOH, at once suggests plausible relationships to all the familiar foodstuff radicals. The fact that small amounts of formic acid are now known to be excreted constantly in the urine makes it appear not improbable that this substance may be formed in the body as an intermediate product of oxidation in large amounts, of which only a very small proportion escapes complete oxidation and is excreted.

Dakin, Janney and Wakeman[1] have started a search for the source of the formic acid which escapes through the kidneys. Some conception of the quantitative relations involved may be gained from the analyses of normal human urines of persons on mixed diets. The formic acid content ranged from 30 to 118 mg. per day, with an average excretion of 60 mg. It is in part of endogenous origin, the output falling during starvation to about one-third the normal amount.

The excretion of formic acid is greatly increased when carbohydrates are given. It is known that many intestinal micro-organisms may not only ferment, but also produce formic acid from both carbohydrates and proteins.[2] Accordingly it might be assumed that the formic acid of the urine has its ultimate source in products of alimentary bacterial activity. This explanation is rendered less tenable by the fact that a marked increase in the urinary output was found to follow the intravenous injection of glucose into the organism. Protein feeding is attended with a similar but smaller increase in formic acid output. Such findings, therefore, point to this compound as a product of the intermediary metabolism of both carbohydrates and proteins. The chemical analogies between some of the processes and products of fermentation and metabolism are constantly being reasserted.

CANCER STATISTICS

The formation of committees and other agencies for the study of cancer in many countries is leading to the collection of data that are of much interest and also in all likelihood of great significance.

As frequently noted, statistics in general seem to reveal an increase in cancer; but whether this may not be the outcome of greater accuracy in diagnosis is a question concerning which there is still a difference of opinion. Obviously, on the basis of the figures and facts now available, the solution of the question as to whether or not cancer is on the increase is most difficult. In the future the conditions for reliable comparisons will be more satisfactory.

The reports on cancer statistics coming from different countries are sometimes so much at variance as to suggest either that the mode of life and external conditions must play a large part in cancer or that the statistics given do not represent the true state of affairs. One example of this discrepancy may be cited. It is generally believed that cancer affects women much more frequently than men. Statistics from England and other countries indicate that it is so; but in Norway this does not seem to be the case.

Soegaard's[1] recent analysis of the statistics gathered in Norway by the Norwegian cancer committee reveals conditions in that country which are highly remarkable. In the first place the figures show a greater number of men to have cancer than women. The difference in favor of men is not large—of 37,046 deaths from cancer during 1865-1895, 18,413 were in men and 18,633 in women, who constitute 51.5 per cent. of the Norwegian population—but the point is that here the conditions noted in many other countries appear to be reversed. The Norwegian statistics also show a preponderance of cancer of the stomach, which is not the case in statistics from other countries. In a series of 9,528 deaths from cancer, 5,990, or 62.9 per cent., were caused by cancer of the stomach. For the ten years 1896-1907 following the period covered by this series, there were 19,263 deaths in Norway due to cancer, of which 12,582, or 65.3 per cent., were from cancer of the stomach. In the province of Nordland there were 1,235 deaths from cancer during 1896-1907, of which 913, or 73.9 per cent., were from gastric cancer. Another remarkable feature of the Norwegian statistics is the comparative infrequency of cancer of the female genital organs in Norway. The highest percentage of any district is only 8.3 per cent., while the lowest is 2.2 per cent. In considering this unusually low percentage Soegaard suggests that the explanation may be the small amount of gonorrheal infection in the Norwegian women.

---

[1] Dakin, H. D., Janney, N. W., and Wakeman, A. J.: Studies on the Conditions Affecting the Formation and Excretion of Formic Acid, Jour. Biol. Chem., 1913, xiv, 341.

[2] For literature on this point see Steppuhn, O., and Schellbach, H.: Ueber die Ameisensäure als Zwischenprodukt der tierischen Zuckerspaltung, Ztschr. f. physiol. Chem., 1912, lxxx, 274.

[1] Soegaard: Die Krebsformen Norwegens, Ztschr. f. Krebsforsch., 1913, No. 13, p. 89.

We see then that the statistics from Norway, evidently gathered with great care and under favorable conditions, differ in three distinct points from the other figures: They show a greater frequency of cancer in men, a greater frequency of cancer of the stomach, and a comparative infrequency of cancer of the genital organs of women. What can this mean? Either that statistics are at fault or that social and other conditions play a decisive part in the development of cancer. If the latter is the case, which seems reasonable enough, the fundamental importance of accurate statistical studies of cancer under different conditions is self-evident. If these studies reveal that in certain countries, communities or districts there prevails cancer of certain organs or of certain types, then the next step would be to discover and eliminate the conditions on which the prevalence depends. There is great need in this country for the accurate study of cancer from this angle.

THE ITINERANT QUACK

The man who comes to the small town with a cheap stock of shoddy clothes, rents a store for a few days or weeks, and by means of flamboyant advertising disposes of his worthless goods to the "suckers" of the locality is looked on by reputable business men as a detriment to the community. Decent men of the town recognize that while the owner of the store rented and the proprietor of the local newspaper may make a little money out of the visit of the fly-by-night merchant, the town as a whole is the worse for the visit. So generally is this admitted that most towns and villages impose a heavy tax on undesirable citizens of this type.

The itinerant quack bears the same relation to the community as the transient clothing-store proprietor, with this difference: while in the one case the unsophisticated are relieved of their money without getting value received, in the other, they also run the risk of losing their health as well. The business men of country towns, however, do not so easily recognize the harm that the traveling doctor does as the damage that the traveling merchant causes. One reason for this is, of course, the fact that the traveling quack is not a competitor of the local business man. Should the local physicians protest, their objections are discounted on the ground that it is a case of "professional jealousy." Rural towns, however, are gradually waking up to the fact that the visit of the itinerant doctor is just as much a calamity as the visit of the itinerant merchant. And, naturally enough, the editors of the country newspapers are among the first to call public attention to this fact. We say naturally because the men editing the country newspapers are, as a class, among the leaders of thought in their communities. From a selfish point of view, the local newspapers might be expected to be the last ones to have anything detrimental to say about the class that brings in a handsome advertising revenue.

The *New Teller* is published at York, Neb. It received an offer of an advertisement from a Dr. A. A. Potterf of Kansas City, who was going to pay a visit to York in the hope, doubtless, of catching some persons who think that their home physicians know less than traveling quacks. Of course the editor did not know that Dr. A. A. Potterf was a graduate of a low-grade homeopathic school that is now out of existence; that while the doctor has been practicing medicine for a quarter of a century he is so little known in his home town that reputable physicians of Kansas City have never heard of him; that in spite of his alleged qualifications, he is not a member of the county or state medical societies. The editor of the *New Teller* did not know, and could not be expected to know, these things; but he did know that physicians who are above the average in knowledge and skill do not go quacking it around the country. Knowing this the *New Teller* published the following open letter on the front page of its issue of July 30. It is worth reading:

> "*Dear Doctor:*—Your ad. copy and express money order received. We regret very much that you contemplate another visit to York in the near future. We regret just as much not being able to keep the money order—it looks good to us. However, the *New Teller* has managed to struggle along several months without any such advertisements. We are mercenary enough to indulge in the hope that you will file your certificate with the county clerk, and pay the small fee required by the law, though this little matter is as a rule neglected by the traveling fraternity of your calling.
>
> "Owing you no personal enmity, we can't help expressing the wish that the city of York might find some way to benefit by your stay in this city to the extent of at least fifty dollars a day. Not so long ago, an itinerant pedler might rent a

> store-room in York, put in a cheap stock of overalls, gilt watches, and in the course of ten days wind up with an auction sale. This proceeding would now cost him too much.
>
> "You may be a good doctor—a most excellent doctor. As such you might build up a lucrative practice in Kansas City and be saved the toils and hardships incident to constant traveling. [A delightful piece of gentle sarcasm.—Ed.] There are already many good doctors in York—plenty, in fact. As they make their homes here, the people have a fair chance to judge them. The people don't have a fair opportunity to become acquainted with you. We believe this community would be as well off without the visits of 'United Doctors,' 'Doctor Specialists,' and the like, and have said so in a variety of ways. We believe the person with defective eyesight should consult an oculist, rather than patronize a spectacle pedler. If pedlers we must have, let them aid materially in cutting down the heavy burden of the taxpayers.
>
> Very respectfully,
>
> The New Teller.
>
> "The above letter also applies to 'The Old Reliable State Medical Institute' of Omaha, which forwards ad. copy under date of July 29, announcing a three days' visit to York. The Institute may be old and it may be reliable. It may be several other things. It should be remembered that a quack doctor is more dangerous and vastly more expensive than patent medicines. The public is now protected to a certain extent against the latter."

Could the facts be stated more simply or more accurately? A letter like this makes the readers of the newspaper think, and quackery cannot thrive among people who think! Some day it will dawn on the public generally that the doctor who can treat any kind of ailment a little better than the general run of doctors does not need to spend money advertising that fact, nor is it necessary for him to assume "the toils and hardships incident to constant traveling!"

THE NATURE OF GENERAL PARALYSIS

The most important advance in our knowledge of general paralysis since its relation to syphilitic infection became generally accepted is the demonstration by Noguchi and Moore[1] of *Spirochaeta pallida* in the brain of paralytics. That their failure to find the spirochete in more than about 25 per cent.[2] to a large extent depended on technical reasons is indicated by the results obtained by Levaditi, Marie and Bankowski.[3] These investigators, using other methods (Fontana, etc.) and examining each cerebral convolution systematically, were able to demonstrate the spirochete in the brains, freshly obtained, from eight of nine cases of typical general paralysis. By the silver method the spirochete was found in only one of the nine cases. It is of importance that in all of the eight positive cases death occurred in a paralytic or apoplectiform attack, whereas in the negative case it occurred as the result of general enfeeblement.

Here, then, is full confirmation and extension of Noguchi and Moore's work. On the basis of their observations, the French workers formulate the etiology and genesis of general paralysis as follows: The disease is the result of the proliferation of the spirochete in the cerebral cortex and of the acute and chronic lesions thus produced. This proliferation occurs in successive crops and in varying localizations, most frequently in the anterior parts of the brain. As the proliferation in one focus ceases, and the parasites die, another may begin in a hitherto intact convolution, thus explaining why a distinct and advanced lesion may not contain large numbers of parasites. Probably the apoplectiform attacks characteristic of general paralysis are connected in some way with proliferative climaxes on the part of the spirochete, particularly when located in motor zones. At any rate the parasite appears to be easy of discovery in the cases in which death occurs in the apoplectiform attack.

General paralysis, then, is the result of actual syphilitic infection of the brain. This knowledge will stimulate the efforts to find some way of arresting this infection, even if it may be impossible to restore the affected parts to their normal state. Efforts will be made also to delve deeper into the nature of locomotor ataxia.

COLD STORAGE AND THE FOOD-SUPPLY

Now that the cold storage business has become a permanent feature of the American food industries, it is a public duty to investigate the varied aspects of this mode of preservation with a view alike of correcting its shortcomings and developing its possibilities. In many quarters the manifold aspects of cold storage and its practical applications to human health and nutrition have not as yet received the serious consideration which the magnitude of the interests involved warrants. Figures sometimes serve as a stimulus for a better appreciation of the facts of commerce and the progress of science. A government report[1] is authority for the statement that the estimated receipts into cold storage during one year amounted in round numbers to 131,000,000 pounds of fresh beef, 20,000,000 pounds of fresh mutton, 176,000,000 pounds of fresh pork, 157,000,000 pounds of butter, and 10,000,000 cases of eggs. It appears that 3.1 per cent. of a year's production of fresh beef, commercial slaughter, goes into cold storage; and the data for the other meats furnish even larger figures. Of the farm and factory production of butter during a year, 9.6 per cent. goes into cold storage, and of the farm and non-farm production of eggs, 15 per cent. The wholesale value of the fresh beef, mutton and pork received into cold storage totaled $35,000,000; of butter, $40,000,000, and of eggs $64,000,000.

Influences of such magnitude bearing directly on so vital a matter as the food factor in national welfare assuredly cannot be overlooked by those interested in the public health. Inasmuch as some of the abuses or objectionable features of cold storage have centered in the unduly prolonged retention of food products, with the consequent possibility of deterioration and incipient decay, instead of perfect preservation, it is interesting to learn in an authentic way something about the actual periods of time during which the food products have in the past actually been subjected to the conservation processes by cold storage in practice. It appears that the receipts into cold storage are entirely or very nearly exhausted by the deliveries within ten months. Very small percentages of some of the commodities were stored for a much longer time, but these are explained by warehouse men as being caused by special circumstances of an uncommercial nature.

---

[1] Noguchi and Moore: Jour. Exper. Med., 1913, xvii, 232. Spirochaeta Pallida in the Brain in General Paralysis, editorial. The Journal A. M. A., March 29, 1913, p. 1002.

[2] Noguchi: München. med. Wchnschr., 1913, lx, No. 14.

[3] Levaditi, Marie and Bankowski: Ann. de l'Inst. Pasteur, 1913, xxvii, 577.

[1] Holmes, G. K.: U. S. Dept. Agric., Bur. Statis., Bulls. 93 and 101. See also Exper. Sta. Rec., 1913, xxviii, 868.

The largest "carry-over" into the second year of storage of the six products investigated has been in the case of dressed poultry, that of eggs being decidedly the lowest. For the average length of time in cold storage the actual costs are surprisingly small, being reported as ranging from a fraction of a cent per pound for meats to 3.5 cents per dozen for eggs—figures representing only a small percentage of the wholesale price of the commodities. If the service thus rendered is a wholesome one, its operations involve a reasonably economical expenditure. In so far as cold storage involves merely a readjustment of price levels, its regulation is a matter of public concern; but that is quite aside from the real hygienic problems concerned therein. We quote the conclusion of the government expert: "Let the fact be what it will with regard to the effect of cold storage on prices, the fact remains that cold storage has been of incalculable benefit to consumers in providing commodities for consumption out of the natural productive season."

SPLENECTOMY AND THE METABOLISM OF IRON

Leon Asher of Berne and his collaborators have devoted considerable attention to the relation of the spleen to the metabolism of iron.[1] It appears from their researches that after removal of this organ from the body, iron is no longer retained as effectively as by the intact organism. There is an augmented continued loss of the element with the feces, an observation that has been confirmed in the case of splenectomized man.[2]

One gains the impression from the studies on record that the spleen is in some way concerned with the conservation of iron. This is strengthened by the added fact that young spleenless animals kept on a diet deficient in iron exhibit a far greater diminution of red blood-cells and hemoglobin than do the normal young of the same species. There is no evidence of an undue destruction of blood elements, for a liberal supply of iron is all that is necessary to develop normal blood conditions even in the absence of the spleen.[3]

Dr. Pugliese[4] of Milan has proceeded with the experimental analysis of this peculiar function of the spleen. Interrelations between the liver and spleen have been asserted to exist. The Italian physiologist has therefore investigated the secretion of bile in the same animal before and after splenectomy. The volume of bile secreted after removal of the organ is, if anything, increased; but the output of iron in the fluid is noticeably diminished thereby. This is explicable in the light of the diminished iron content of the liver that may be expected in persons losing undue amounts of iron with the feces. Pugliese has further demonstrated a diminution of the iron in the blood, along with the decrease in erythrocytes and hemoglobin, in the early period after splenectomy. This does not persist very long, however, before a recovery of normal conditions in the blood ensues. The facts confirm what we have earlier pointed out, namely, that with a suitable diet the nutritive outcome of splenectomy need not be in any way unfavorable.

Current Comment

"SCORING" THE MILK SELLER

We recently discussed some of the factors which demand consideration in the present attempts to improve the quality of the milk-supply to cities, and offered some comment on the limitations which affect the producer.[1] A still different aspect of the subject has been raised by the investigator in charge of the market-milk investigations of the Bureau of Animal Industry.[2] He remarks that it has been a too prevalent custom in the past to lay all of the blame for dirty milk on the shoulders of the milk producer. While this may be an easy and convenient way, he adds, to shift the burden of responsibility from city to country, it is apt not only to hurt the dairy industry unfairly, but to close the eyes of reformers and health authorities to questions that lie nearer home. Milk inspection, to be complete, must apply to the places and modes of delivery quite as well as to the farm and its environment.

Precisely as systems of "scoring" dairy farms have been planned and are actually in operation as a basis for selling graded milk, so it is now proposed to devise a scheme of inspection and method of control for the stores and distributing plants concerned in the milk industry. There is the widest variation in the practices now prevalent in our American cities. In some there is rigorous control exercised by efficient health authorities, under whom a "license" or a "permit" carries with it an assurance of reliable supervision. In other places there are dead-letter regulations or no laws whatever. There are communities in which the sale of milk in bulk is forbidden; elsewhere it is freely tolerated.

The conditions essential for the preservation and delivery of milk in a sanitary condition are now well known in a professional way. It is perhaps not too early, therefore, to bring pressure to bear at every point at which a violation of the necessary provisions spells failure. To attempt to "standardize" stores handling milk and to rate them in the public eye along the lines which are followed by the inspectors who safeguard the sources of supply of cities like New York, may be premature in 1913. High ideals are worth striving for. It is not difficult to educate an interested public by a system of propaganda. Drastic ordinances cause unnecessary hardships and friction. The fortunate community is one that succeeds in securing cooperation at every step, first by inculcation and then by liberal enforcement of reasonable measures.

MEANING OF THE WORD "CURE"

Recently we commented on the misinformation frequently given the public through the newspapers by the incorrect translation of the word "cure" or *Kur* from medical reports in foreign languages.[1] Another instance of the mistranslation of the word "cure," which in foreign tongues means only care or treatment, is taken from an item in an Italian medical journal on the subject of large medical fees. The item cited refers to the late J. P. Morgan, and a portion of the original item showing the use of the word "cure" may be quoted in the original Italian:

> Le quattrocentomila lire di compenso fissate ai medici che *curarono* Morgan durante l'ultima sua malattia fanno ricordare altri casi di colossali onorari a sanitari illustri.

This is the way it was translated:

> The $80,000 awarded to the physicians who cured J. P. Morgan during his fatal illness brings to mind other large fees paid to illustrious members of the medical profession.

CONSCIENCE AND VACCINATION

To any one to whom figures mean anything or who is willing to accept the *absolutely* undoubted results of experience, vaccination as a preventive of small-pox is an established fact. If the good of the whole people is to be regarded as a principle of disease prevention as it is in other matters of government, then vaccination should be universally compulsory. That it is not so
a reflection on the good sense and good judgme[illegible]ly
enlightened people. We find, however, that in general

centage of persons exempted from vaccination on account of conscientious objections as compared with the total number of births from 1907 to 1912 increased from 6.3 per cent. in the former year to 17.3 per cent. in 1908 and thence rapidly to 31.6 per cent. in 1912. The tolerance of a privilege which permits one out of three persons practically to nullify the effect of a proved preventive health measure is an absurdity in this day, and will merely result in a large measure in return to the horrible small-pox conditions of former days in Great Britain. The prevalence of small-pox in the United States during the past year is no doubt due to the absence of strict regulation in regard to vaccination, the lax enforcement of regulations already provided or the total ignoring of these regulations. The matter of vaccination should nowhere depend on any sort of objections of an individual, but should be determined solely by scientific and statistical knowledge.

THE "COLLOIDAL NITROGEN" OF THE URINE

Almost from time immemorial the urine has been called on to bear the burden of many of the uncertainties that are involved in the subtle and ever-changing art of diagnosis. Color and consistency, odor and transparency, have been clothed from time to time with some unique temporary significance that has been dispelled in turn with the progress of investigation. When real knowledge is wanting, the distinction between the initiated and the novice, the bona-fide student and the impostor is not always easily drawn.

It is a common experience to find new "discoveries" invested with some unusual import. We recall the controversy which centered about the alleged finding of "ureine" as a significant constituent of the urine a few years ago. Now this hypothetic substance has completely lost its identity and the name itself is probably unrecognized by the student of to-day.

A few years ago considerable was written regarding

THE PATHOGENESIS OF ARTHRITIS

There is food for thought in a paper by Beitzke which reports the results of a study of the joints in two hundred necropsies in the Pathology Institute at Berlin.[1] This work was the continuation of a study carried out in the same laboratory by Rimann which had disclosed that in the bodies of one hundred persons, in age ranging between 15 and 80 years, alterations were visible in the knee-joints of no fewer than sixty-seven. This surprisingly large incidence of joint changes in persons not considered to be arthritics is more than corroborated by Beitzke's investigation. He examined in two hundred bodies not only the knee-joints, but also the joints at the base of the great toes and often the hip-joints and shoulder-joints, finding in this series but thirty-five who did not have lesions in at least one of these joints. Of the total number there were six cases of ordinary arthritis deformans and in sixteen there were some evidences of gout, so that of 178 bodies of persons without these typical joint diseases there were macroscopically visible changes in the joints in at least 143. The lesions varied from areas but a few millimeters in diameter in which the cartilage was thinned and degenerated, up to erosive changes destroying practically all the cartilage, associated with fibrotic alterations in the underlying bone tissue. Essentially there is no difference between these lesions and those of atrophic arthritis deformans, and the conclusion seems warranted that they are the result of the trauma of every-day life from which all persons suffer, and that they constitute a *locus minoris resistentiae* which determines the action of bacterial products, or of the bacteria themselves, in persons suffering from chronic infections. They are present alike in the two sexes, and increase in frequency with age, the figures being 60 per cent. in persons from 20 to 40 years old, 95 per cent. between 40 and 50 years, and practically 100 per cent in older persons. In these findings a ready explanation is seen of the great
frequency of arthritic disease, and it becomes easy to

nue and Sixteenth Street, Chicago, beginning September 24, at 9:30 a. m. No one will be admitted to the examination unless he presents a card of admission which will be issued to any applicant whose application is received on or before September 16. Application should be made to the Acting Secretary of the State Board of Health, Springfield.

Additions to University Faculty.—The following appointments to the faculty of the University of Illinois were announced by the president, August 26: Dr. Albert C. Eycleshymer, St. Louis, professor of anatomy and head of the department of anatomy of the medical school; Dr. Richard Rupert, Chicago, instructor of anatomy; Dr. George P. Dreyer, Chicago, professor of physiology and head of the department of physiology, school of medicine; Dr. Bernard Fantus, Chicago, professor of pharmacology; Dr. Edgar Grim Miller, Columbia, Pa.; Dr. J. Craig Small, Chambersburg, Pa., and Dr. H. N. Walker, Harrisburg, Pa., assistant professors of physiologic chemistry; Dr. Edgar D. Coolidge, Chicago, professor of materia medica and therapeutics; and Dr. Louis Schultz, Chicago, assistant professor of oral surgery and pathology.

Personal.—Dr. Perry H. Wessels, Jr., has been reappointed city physician of Moline.——Dr. John P. Benson, Joliet, has been appointed physician at the State Penitentiary.——Dr. J. S. Mason has been elected president, Dr. A. Darwin Kirby, vice-president and Dr. W. M. Honn, secretary of the medical staff of the Julia F. Burnham Hospital, Champaign.——Dr. Paul Sherman, Shawneetown, has been appointed inspector of the State Board of Health.——Dr. and Mrs. W. Grant Hatch, Rockford, sailed for Europe, September 3.——Dr. Anna Dwyer, Chicago, has been appointed a member of the State Charities Commission, vice Dr. John T. McAnally, Carbondale, resigned. ——Dr. William Barnes, Decatur, is convalescent after an operation for appendicitis.——James Mullenbach has been appointed superintendent of the Cook County Institutions, Oak Forest.——Dr. George S. Rainey has been elected a member of the Common Council of Salem.——Dr. J. L. Aleshire, Plainville, was operated on for appendicitis August 11, and is doing well.——Dr. G. F. Tyson, Evanston, has started for Europe.——Dr. J. F. McCutchan, Alexis, celebrated his eightieth birthday anniversary, August 9.——Dr. Mathilda Freitag, Savage, was stricken with appendicitis while traveling in Holland, recently, and was operated on, and is reported to be making satisfactory progress toward recovery.

Chicago

Physician Exonerated.—Dr. A. E. Ludwig, charged with having caused the death of Mrs. Marie Lucas through an operation, was exonerated by the coroner's jury, August 14.

Health Commissioner to Handle Garbage Plant.—Dr. George B. Young, commissioner of health, has been placed in charge of the new city garbage reduction plant to be acquired from the Chicago Reduction Company under the ordinance recently passed.

MASSACHUSETTS

Personal.—Dr. Arthur Allison Howard has been appointed physician-in-chief of the Hospital for Children and of the Children's General Outpatient Department of the Boston Dispensary, succeeding Dr. William Palmer Lucas, resigned.—— Dr. John H. Cain has received the appointment of postmaster be Lexington.

MICHIGAN

New Officers.—Upper Peninsular Medical Society at Ishpeming, August 6-7: president, Dr. H. J. Hornbogen, Marquette; vice-presidents, Drs. George G. Barnett, Ishpeming, and C. F. Moll, Kenton. Houghton was selected as the meeting place for 1914.

State Farm for Epileptics.—The Governor, the Secretary of the State Board of Corrections and Charities and the State Health Officer recently looked over the proposed site for the new epileptic colony near Ann Arbor. The new institution will be on the lines of a colony settlement and segregation will be one of the principle factors.

Personal.—Dr. Angus McLean, Detroit, has returned from Europe.——Dr. W. S. Mackenzie has succeeded Dr. Clifford C. Kirkpatrick as local surgeon for the Wabash System at Adrian.——Dr. R. W. Hodges, Freda, has succeeded Dr. W. D. Whitten as surgeon at the Baltic Mine and Dr. H. D. Cornell, Victoria, has been appointed surgeon at Freda. Dr. Whitten will locate in Southern California.——Dr. R. D. Sleight, Battle Creek, has returned from Europe.

MINNESOTA

Tax Assessed on Physicians.—On the assumption that physicians have money in the form of bonds, stocks and notes, the Ramsey County Board of Equalization has directed the county assessor to assess every physician whose name appears in the city directory, from $500 to $1,000 for moneys and credits.

The Vincent Plan.—President Vincent's plan to readjust the university clinical staff at the city and county hospital, St. Paul, was considered by the Board of Control, August 18. Under the proposed plan, the university staff will concentrate its work in the period of six months and according to the superintendent of the hospital, the plan can be put into operation without making any very radical changes.

Personal.—Dr. L. M. Brunet, Duluth, has resigned as agency physician at Nett Lake and will resume practice in Superior, Wis.——Dr. B. E. Hempstead, Duluth, has started for Europe. ——Dr. William D. Kelly, St. Paul, has succeeded Dr. John T. Rogers as chief of the staff of the city and county hospital and Dr. Frederick E. Leavitt has been elected secretary of the staff——Dr. E. W. Buckley, St. Paul, has been elected supreme physician of the Knights of Columbus.

MISSOURI

Personal.—Dr. J. R. Ernest, Kansas City, Kan., has been appointed surgeon in the United States Coast and Geodetic Survey service.——Dr. George H. Jones, Kansas City, has been appointed State Bacteriologist, vice Dr. M. C. Stone, Jefferson City, resigned.——Dr. R. O. Lieuallan, Mercer, has succeeded Dr. A. H. Vandivert as assistant physician at State Hospital No. 2, St. Joseph.——Dr. E. H. Trowbridge, assistant physician at State Hospital No. 2, St. Joseph, has been appointed assistant superintendent for the Minnesota School for Feeble-Minded and Colony for Epileptics at Faribault.——Dr. J. F. Binnie, senior attending surgeon to the Kansas City General Hospital, has resigned.

St. Louis

Sanatorium Fund Nearly Ready.—There is only needed $2,872 to complete the $50,000 fund necessary to secure for the Missouri Baptist Sanatorium, the subscription of $100,000 made by the late A. D. Brown.

Leper Escapes.—George A. Hartman, who was examined and pronounced a leper several weeks ago and was assigned to the Carter Camp 14 miles south of St. Louis, escaped for the second time in three weeks, August 27.

Hospital Library Plan.—The City Hospital Board has taken up the matter of installing a medical library at the city hospital for the benefit of its interns. A part of a fund of $500 is said to be available for this purpose, and contributions of books have been offered by members of the staff and others.

NEBRASKA

Hospital Notes.—Germans of Omaha propose to build a new hospital and deaconess home in that city. The hospital work will be in charge of the German Samaritan Hospital Association, an interdenominational organization which includes all the German churches in the city.——Ground was broken recently at Hastings for the Mary Lanning Hospital which is to be erected by W. H. Lanning in memory of his daughter. ——Although the last legislature appropriated funds for a new building at the Norfolk State Hospital to relieve the present crowded conditions, no action has yet been taken by the Board of Control.

Personal.—Dr. W. D. Guttery, Pilger, has been appointed superintendent of the State Hospital for the Insane, Norfolk. ——Dr. E. M. Whitten, Nebraska City, is reported to be seriously ill.——Dr. Amy R. Robinson, Hastings, who has been seriously ill with ptomaine poisoning, is said to be convalescent.——Dr. R. L. Ivins, Harrison, has returned from Omaha, convalescent, after an operation for the removal of the appendix.——Dr. H. R. Carson has been appointed first assistant physician at the State Hospital, Norfolk, and Dr. R. H. Foster, Omaha, has been made second assistant physician.——Dr. Nellie G. Carr, Deffenbaugh, Grand Island, has been appointed superintendent of the State Tuberculosis Hospital, Kearney. ——Dr. LeRoy Crummer, Omaha, has returned from Europe. ——Dr. W. H. Wilson, Table Rock, has been reappointed state health inspector.——Dr. Elmer R. Porter, Omaha, has recovered $1,190 for medical services rendered the late Anna Williams. His original claim was for $5,000.

NEW YORK

New York City

Another Decrease in Infant Death Rate.—The figures for the infant mortality for the week ending August 23, showed a decrease from the number of deaths reported for the corresponding week of 1912. There were only 340 deaths as compared with 350 for the corresponding week of last year. The reductions were in Brooklyn and the Bronx.

Atmospheric Conditions in City Schools.—The report of the Committee on School Inquiry of the Board of Estimate and Apportionment has been submitted by Prof. Charles Baskerville and Prof. C. E. A. Winslow who worked with Prof. Paul H. Hanus of Harvard in making the investigation. Some of the conclusions reached were that some of the best and some of the worst ventilated schools were fan-ventilated and that the whole problem rested on the skill with which the fan system was operated. It was found that the air in the schoolrooms investigated was good in so far as dust was concerned, the number of bacteria, moulds and microbes being small. In regard to temperature it was found that out of 1,800 determinations only 14 per cent. were over 71 degrees F., indicating that overheating is rare. In about one-sixth of the schoolrooms investigated the conditions were distinctly bad, but this was due to the carelessness of janitors and the interference of teachers rather than to construction. It was found that air conditions in the night-schools were not as good as in the day-schools, owing to the fact that the ventilating systems frequently are not operated at night.

Court Upholds Oral Agreement.—In January last Dr. James P. Tuttle, since deceased, operated on James R. Keene, the latter dying the same day. Dr. Tuttle then presented a bill to the estate for $5,200, which he said was in accord with an oral agreement with the patient. The executors of the Keene estate claimed that the bill was excessive, but permission has been granted by the court to settle with Dr. Tuttle's estate for $4,000.

Personal.—Dr. Louise Pearce of the Johns Hopkins Hospital has been appointed as assistant to Dr. Simon Flexner at the Rockefeller Institute for Medical Research.——Dr. and Mrs. Theodore C. Janeway, Dr. William L. Culbert and Dr. Howard Fox, have recently returned from Europe.——Dr. Lester M. Hubby and Dr. Emil Frei of Brooklyn have sailed for Europe.

NORTH CAROLINA

Physician Acquitted.—Dr. E. A. Hennessee, Glen Alpine, who killed a man in a street duel a few months ago, was tried last week and acquitted. Dr. Hennessee himself sustained several injuries including a penetrating gunshot wound of the lung.

Personal.—Dr. Platt W. Covington, formerly of Wadesboro, who has been doing acceptable work in the hookworm department of the State Board of Health for two years past has been placed in charge of the newly created Board of County Health with headquarters in the department of Public Health, Raleigh. The aim of this department is to care for and develop interest in county health work throughout the state and especially to facilitate health work in those counties where a whole-time health officer is in charge.——Dr. S. Westray Battle, Asheville, has sailed for Europe.

OHIO

New Hospital for Port Clinton.—Dr. Henry J. Pool has purchased the Carrothers residence on East Second Street, Port Clinton, and has converted it into a private hospital.

Physicians Named for Poor.—Safety Director Mooney, Toledo, has announced the appointment of the following twelve physicians to render aid to the indigent poor: Drs. Geo. L. Chapman, Helen M. Nolen, W. E. R. Schottstaedt, James G. Cullen, Dalton Kahn, Leo S. Talaska, James C. Price, Emily C. Willoughby, Edwin C. Ballinger, Robert E. Lawless, Frank C. Titus, and Charles H. Ferguson.

Personal.—Dr. H. L. Sanford, Cleveland, has been appointed member of the Board of Health vice Dr. J. E. F. Cogan, retired.——Dr. Wm. L. Neville, Lima, has been appointed a trustee of the Lima Hospital, succeeding Dr. F. M. Hassey, Sidney, who was recently appointed superintendent of the institution.——Dr. Wm. R. Dabney, Marietta, is said to have become demented while performing an operation in Dayton, October 12, and to have been committed to Longview Asylum, Cincinnati.——Dr. and Mrs. Tenney, Toledo, have sailed for Europe.——Dr. Charles S. Means, Columbus, is reported to be ill with typhoid fever.

PENNSYLVANIA

Campaign Against Quacks.—The York County Medical Society has started a campaign against quacks, a committee on illegal practice having been appointed with instructions to proceed with prosecutions against alleged offenders.

Typhoid Fever in the State.—Typhoid fever has again appeared at Royersford, seven cases having been reported within the past week. Many cases of typhoid have been reported throughout the outlying districts of Winslow.

Personal.—Dr. John W. Phillips, Troy, has sailed for Europe.——Dr. J. T. Eckert, Allentown, suffered a fracture of both clavicles by the overturning of his automobile, recently.——Dr. John A. McKenna and family, Landsdowne, sailed for Europe, August 9.——Dr. and Mrs. Charles S. Rebuck and son, Harrisburg, have returned from Europe.

Hospital News.—The bids for the erection of the new Hospital for the Insane of Westmoreland County were opened August 12. The lowest bid was $331,200.——The bids received for the construction of St. Mary's Hospital, South Scranton, were all above the figure which the hospital could afford to pay, and further progress in the matter has been deferred indefinitely.

Philadelphia

Increase in Typhoid.—Seventy-four new cases of typhoid with ten deaths were reported to the Bureau of Health for the week ended August 30, an increase of 25 over the preceding week.

Baby Saving Show at Public Disposal.—After October 1, the Baby Saving Show will be removed from its present quarters in the City Hall and placed at the disposal of the public. In order to place the exhibit before the parents of the city, the Child Hygiene Association has asked that applications for the show in different neighborhoods be sent in as soon as possible.

Little Mothers' Clinics.—The success of the Little Mothers' Clinics held at the mission house at Tenth and Kimball Streets, proved by the attendance of more than fifty little Italian girls carrying their small charges at the third clinic and their interest in the instruction given. The ages of the children ranged from 5 to 8 and they were in charge of Dr. Mary Fallon.

Public Works Department to Ask City to Build Garbage Plant.—At the next meeting of the City Council, Director Cooke of the Department of Public Works, will submit plans and estimates for a city garbage plant. The complete proposition includes: Construction of municipal garbage reduction plant with collecting equipment to cost approximately $1,000,000. Abolition of pigs and piggeries within the city limits. Use of closed metal garbage cans by every householder in the city. Since 1905, the city has spent nearly $4,000,000 for the collection and disposal of its garbage and there have been complaints and protests from all parts of the city of the lax and irregular collections.

Personal.—Dr. George P. Mueller has been elected professor of surgery in the Philadelphia Polyclinic, succeeding Dr. Lewis W. Steinbach, deceased.——Dr. Mary W. Griscom sailed for Europe, September 2, en route to Korea by way of Siberia.——Dr. J. William White sailed for Europe August 16 and will be abroad for eight months, returning by way of China.——Dr. William Gautner of the Philadelphia Hospital for the Insane, has been appointed assistant physician at the new State Hospital, Pottsville.——Dr. George C. Signor has been elected superintendent of the Eastern Pennsylvania Institution for the feeble-minded and epileptics, near Spring City, vice Dr. H. M. Carey, resigned.——Dr. Henry F. Page, medical superintendent of the German Hospital, was seriously injured by being thrown from a carriage in a runaway near Bangor, Me.——Dr. Eric S. Wischeart, for two years senior house physician at the Presbyterian Hospital, has resigned to enter practice in Snow Hill, Md.

WASHINGTON

Harvard Professor in Seattle.—Dr. Joel E. Goldthwait, Boston, a member of the faculty of the Harvard Medical School, was the guest of the King County Medical Society, Seattle, at luncheon, August 12, and addressed the organization on the subject of "Visceral Ptosis."

Personal.—Dr. W. E. Cass, Vancouver, has been appointed superintendent of the Northern Hospital for the Insane, Cedro-Woolley.——Dr. E. W. Fell, Medical Lake, has been appointed assistant physician of the Elgin (Ill.) State Hospital.——Among those in attendance at the seventh annual pilgrimage of the mountaineers in the Olympian mountains, were: Drs. F. W. Griener, Ballard, and N. P. Wood, Seattle.

WISCONSIN

Will Select Site for Camp.—The State Forester and Dr. J. W. Coon of the State Tuberculosis Sanatorium, Wales, have been authorized by the State Board of Control to select a site in the Forestry Reserve for an experimental tuberculosis camp.

Tuberculosis Notes.—The revised plans for the proposed municipal hospital at Waukesha call for an expenditure of about $12,000. The institution will accommodate from fourteen to sixteen patients.——Drs. D. R. Connell and H. C. Maurer, Beloit, have purchased the old St. Mary's Hospital building in that city and will, it is expected, open a hospital in the near future.——At the semi-centennial celebration of the Milwaukee Hospital, it was announced that a gift of $100,000 had been made to the institution by Mr. Frederick Layton.

Personal.—Dr. Edward Kremers, Madison, had conferred on him the honorary degree of D.Sc. by the University of Michigan, Ann Arbor, recently.——Dr. Frank I. Drake, Madison, has been elected physician of the State Penitentiary, Waupun, vice L. Rock Sleyster, who has been made superintendent of the State Hospital for the Criminal Insane.——Dr. H. A. Norden has resigned as health officer of Sturgeon Bay, to accept the position of superintendent of the Chicago-Winfield Tuberculosis Sanatorium, near Chicago.——Dr. Belle P. Nair, Fort Atkinson, has been appointed resident woman's physician at the Northern Hospital for the Insane, Oshkosh.——Dr. Leopold Schumacher, first assistant on the medical staff of the University of Wisconsin, in charge of students' health, has resigned and will practice in Chattanooga, Tenn.

GENERAL

Tuberculosis Sunday.—The National Association for the Study and Prevention of Tuberculosis announces that Sunday, December 7, has been designated as the fourth annual tuberculosis day at which special efforts will be made through churches and otherwise to interest the people in this most important subject.

Bequests and Donations.—The following bequests and Donations have recently been announced:

Industrial School for Crippled and Deformed Children, Boston, $30,000. Children's Hospital, Boston, $10,000. Boston Home for Incurables, Boston Dispensary, Boston Nursery for Blind Babies and the District Nurses' Association, each $5,000 by the will of Amos Cotting, Boston.

Pottsville (Pa.) Hospital, $30,000 by the will of Mrs. James Muir.

Chautauqua County Tuberculosis Hospital, $150,000 by the will of Mrs. Elizabeth M. Newton, Fredonia, who died recently in California.

Gorgas to Go to Africa.—In despatches from Johannesburg, South Africa, under date of August 14, it is stated that Colonel William C. Gorgas has received an invitation from the Chamber of Mines, Johannesburg, to visit South Africa, study the sanitary conditions in the Witwatersrand mines and to make suggestions as to their improvement. The special object of the conference is the prevention of epidemic pneumonia of a very fatal type among the blacks such as occurred several years ago among the negro laborers at Panama and was successfully handled by improvement of the sanitary conditions. Colonel Gorgas has accepted the invitation subject to the approval of the United States Government, and has applied for leave of absence of four months to enable him to make the journey and complete the research required.

Library of Radiographs.—An attempt is being made to establish, at the Army Medical Museum, Washington, D. C., an extensive library of lantern and stereoscopic slides of radiographs, representing the work of radiographers who have done particularly notable work along certain lines. Enough slides have already been received to make the collection of value for reference and for teaching purposes at the Army Medical School. Those who have already contributed to the collections are Dr. Lewis Gregory Cole, New York City, slides of stomach, lung and kidneys; Dr. William H. Dieffenbach, New York City, slides of diseases of bones; Dr. Kennon Dunham, Cincinnati, Ohio, stereoscopic slides of the lungs; Dr. Walter C. Hill, Cleveland, Ohio, slides of diseases of bone; and Dr. James T. Case, Battle Creek, Mich., slides of the alimentary tract. Others have promised to send slides, and it is the intention to add to the collection from time to time as important work is done. The collection is available for study by any civilian practitioner on application to the curator, Army Medical Museum, Washington, D. C.

Would Transform Battle Ships into Sanatoriums.—At the closing session of the Fourth International Congress of School Hygiene in Buffalo, August 29, the following resolutions were offered by Dr. S. Adolphus Knopf, New York City, and were adopted without discussion:

> WHEREAS, Nearly a million tuberculous children or children simply predisposed to tuberculosis are attending our public schools, and there is hardly accommodation for 1,500 to receive instruction in the open air; and
>
> WHEREAS, The Congress is convinced that the open air school is one of the most powerful agents in the prevention and cure of tuberculosis in childhood, and it has been furthermore demonstrated that nearly all climatic conditions, providing the air is dust-free, lend themselves to the prevention of tuberculosis in the predisposed and the cure of the afflicted; and
>
> WHEREAS, Statistics show that there are not nearly enough hospital and sanatorium accommodations for adults and children afflicted with pulmonary tuberculosis or children suffering with tuberculous joint or bone diseases; and
>
> WHEREAS, It has been demonstrated in New York and other cities that discarded vessels lend themselves admirably to transformation into all-year-around hospitals and sanatoria for consumptive adults, sanatoria for children afflicted with joint and other types of tuberculosis, and into open air schools for tuberculous, anemic, and nervous childrden;
>
> *Resolved,* That the Fourth International Congress on School Hygiene petitions the United States government to place at the disposal of the various States of the Union as many of the discarded battleships and cruisers as possible to be anchored according to their size in rivers or at the seashore and to be utilized by the respective communities for open air schools, preventoria, sanatorium schools for children, or hospital-sanatoria for adults. Be it further further
>
> *Resolved,* That the Congress expresses its appreciation to the Italian government of the example it has given by consecrating three of its discarded men of war to the combat of tuberculosis. Be it further
>
> *Resolved,* That this Congress expresses the sincere wish that other governments may fellow the example of Italy; and be it finally
>
> *Resolved,* That copies of these resolutions be presented to the American and other governments represented at this Congress.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, August 15, 1913.

Personal

Dr. Lacassagne, professor of legal medicine at the Faculté de médecine de Lyon, who is well-known as the founder and director of the *Archives d'anthropologie criminelle,* has just retired. His place is taken by one of his pupils, agrégé E. M. Martin.

The death of Dr. Bourget, professor of clinical medicine and internal pathology at the Faculté de médecine de Lausanne, is reported.

Irradiated Vaccines

At one of the last sessions of the Académie des Sciences, Dr. Maurice Renaud read an interesting paper on the irradiation of bacteria and irradiated vaccines. He found that bacteria exposed to the radiation from a quartz lamp with mercury vapor are deprived of all their biologic properties while they keep their histochemical properties, and in particular their toxicity. If in man or in animals irradiated cultures of pathogenic microbes are injected, no infectious disease results. Moreover, the inflammatory phenomena at the point of injection are usually insignificant, and the bacteria disappear from the tissues with remarkable rapidity. This resorption creates a condition of intoxication which leads to immunization with appearance of antibodies in the body fluids. Because of these properties of irradiated bacteria it occurred to Renaud to utilize them as vaccines. For two years he has used them for preventive and therapeutic immunization in men, and they have given him, especially in the cases of the staphylococci, streptococci, gonococci, etc., results much superior to those of vaccines obtained by the coagulating action of heat or of chemicals.

Measures against Typhoid Fever

The minister of the interior has just sent to the prefects a circular inviting them to make public in their departments the advantages of the two antityphoid vaccines which have been authorized by a recent decree and which are prepared respectively in the laboratory of Professor Chantemesse at the Faculté de médecine at Paris and in the laboratory of antityphoid vaccination of the Ecole d'application de médecine et de pharmacie militaires at Val-de-Grace. When cases of typhoid fevr which seem likely to give rise to an epidemic occur, the various health officials and the mayors are to place at the disposal of physicians the necessary supply of either vaccine. The minister of the interior, moreover, recommends to the prefects to have the water supply improved hereafter if necessary.

Protection of Women Before and After Childbirth

A woman employed by a merchant brought suit against her employer for $40 (200 francs) for not having given her back the position which she held before the birth of a child. The employer maintained that he owed his former employee at most only a week's wages in lieu of notice. The court, however, held that under the law of November 27, 1909, the woman was entitled not only to the ordinary indemnity for dismissal but also for damages.

Examinations for the Doctor's Degree

Up to the present a medical student who has failed in an examination may present himself for the same examination at the end of three months. A recent decree provides that after four failures on the same examination the candidate may not try again for two years.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, Aug. 22, 1913.

Personal

Honorary Professor Goldmann, head surgeon at the Deaconess House in Freiburg, died, August 11, aged 51. Goldmann, who was for many years assistant to Professor Kraske, was a capable investigator who had particularly of late years received general recognition for his researches on vital staining.

Professor Bardenheuer of Cologne died, August 13, at the age of 72. He was one of the most noted surgeons of Germany. His scientific labors were performed especially in the field of fractures and dislocations. His method of treatment by permanent extension has become general. He has also published important contributions in many other fields of surgery. In "Deutsche Chirurgie" he wrote the section on injuries of the extremities. In 1889 he published a manual on the treatment of fractures and dislocations by means of extension (Leitfaden der Behandlung der Frakturen und Luxationen mittels der Extensionsbehandlung).

The Future of the Berlin Krankenkassen

The new imperial insurance law to which I have repeatedly referred requires one general local Krankenkasse in every city so that marked changes must be made in the organization by Jan. 1, 1914, when the new law goes into effect. Many of the other kinds of insurance organizations such as the trade societies, the Innungskrankenkassen, the free aid societies, will be absorbed by the future consolidated local societies.

At present there are in Berlin 54 local societies with about 600,000 members, 69 trade societies with about 165,000 members, 19 Innungskrankenkassen with about 60,000 members and 20 free aid societies with about 35,000 members. According to the new arrangements the membership of the consolidated local society will increase from about 90,000 to about 400,000 and probably will exceed a half million. It is clear that with these extensive changes the relations of physicians will also be disturbed.

As a number of Krankenkassen with free choice of physician are to be dissolved, the number of physicians engaged in insurance work will be materially diminished. On the other hand there will be an increase in the extent of the limited free choice of physician, by which under certain conditions a fixed number of physicians do the work of the societies among whom the insured have free choice. The mass of the insured laborers will secure an advantage from the new organization because, on account of the increased membership of the single societies, these may extend their operations and because there will be less frequent changes of membership in the societies on account of change of occupation, changes which naturally occur much more easily with a smaller membership. At present negotiations are under way between the representatives of the insurance physicians and of the Krankenkassen to secure an agreement on a satisfactory basis between the various interests.

Further Reduction of the Prussian Birth-Rate

The latest statistics show a decline of the birth-rate, the births being 3,156 less than the previous year, a reduction of 1.1 per cent. A reduction in the excess of births over deaths is averted by the fact that the exceptional mortality of 1911 was not repeated in 1912. An increase in the number of marriages is also to be noted.

Increase in Cancer

Recent statistics show a constantly increasing proportion of deaths from cancer, the mortality in 1911 being nearly five thousand more than in 1907. More men than women and more married than single fall victims to the disease. The increase with advancing age is marked. The increase in the mortality per ten thousand is as follows: 1907, 6.57; 1908, 6.60; 1910, 7.04, and 1911, 7.28. The proportion among men rose from 6.03 in 1907 to 6.64 in 1911, and among women from 6.57 to 7.28. Among the unmarried in 1911 there were only 1.09 deaths from cancer per ten thousand living, while among the married the figure was 12.29; among the divorced, 24.09, and among the widowed, 41.79.

Mental Diseases and Occupation

The National Statistical Bureau at Karlsruhe has caused a statistical investigation to be made with reference to the occupations followed by the persons who were admitted to the national sanatoriums and asylums of the grand duchy of Baden during the seven-year period from 1904 to 1910. These statistics include 15,980 insane persons above 16 years of age, of whom 8,678 (54.3 per cent.) were male and 7,302 (45.7 per cent.) were female.

The principal result is a confirmation of the prevailing view that persons engaged in intellectual occupations are chiefly exposed to the danger of mental disease. Of the 15,980 patients, 3,278 belonged to agricultural and forestry employments (1,867 males and 1,411 females); 6,159 persons were employed in trades (3,997 males and 2,162 females); 2,404 in commerce (1,485 males and 919 females); 1,351 (683 males and 668 females) in the so-called free professions (clerks, officials, artists, etc.).

For every thousand persons belonging to a particular employment, there were in June, 1907, 7.8 *insane* (9.4 males and 6.3 females) in agriculture and forestry; in trades 12.1 (13.9 males and 10.2 females); in commerce 14.7 (18.5 males and 11.0 females), and in the free *professions* 16.5 (13.3 males and 19.6 females).

From these relative figures it is plain that of all professions, those engaged in agriculture *and forestry* are least in danger of mental disease. The most liable to mental disease are those belonging to the so-called free professions. Men in all departments of industry are *more* exposed to mental disease than women, with the exception of the free professions, in which the proportion of the female sex (19.6) is far in excess.

If household servants are excluded, the following picture presents itself: 7.4 out of every thousand of those actually engaged as *independent workers* in the agricultural and forestry profession, 13.1 per thousand of those engaged in trades, 19.2 of those engaged in commerce, and 22.5 of those in the professions are subject to *mental* disease.

The danger of mental disease is much less for those who are subordinate workers in each occupation: In agriculture, 5 per thousand; in *the trades*, 12.9 per thousand; in commerce, 12 and in the free professions only 10.3 per thousand of the employees were subject to mental disease, with males predominating.

There were admitted to the sanatoriums in the period from 1904 to 1910 on account of alcoholic insanity or of chronic alcoholism, a total of 1,030 men (1.6 per cent.), and 89 women (0.1 per cent.); on account of paralysis, 748 men (1.1 per cent.) and 216 women (0.3 per cent.); on account of neurasthenia, 324 men (0.5 per cent.) and 43 women (0.1 per cent.); on account of epilepsy 681 men (1 per cent.) and 191 women (0.3 per cent.). This finding corresponds to the well-known fact that the male sex is exposed to a much greater extent than the female to the danger of alcoholic excess and the results of venereal infection (progressive paralysis) and the danger of over-exertion in mental work and neurasthenia.

The *number of independent* male workers affected with alcoholism increases to 6.1 per cent. in the commercial class in which the inn-keepers and saloon-keepers are included; 23 men, including 13 physicians, were admitted to these institutions on account of addiction to morphin or similar narcotic poisons. Paralysis and neurasthenia are prominent, totaling 3.3 or 1.3 per thousand of those engaged among government employees, professional persons and artists and particularly among those who are independent workers.

Among the women admitted, simple mental disturbance was the *most prominent* (6,003 cases, or 9 per cent.). This is explained by the well-known greater tendency of the female sex to emotional disease (melancholic depression, maniacal excitement, etc.), as well as to hysteric affections. Among simple mental disturbances are reckoned also the mental affections which occur in connection with reproduction (pregnancy, labor and the puerperism).

Organization of School Physicians in Würtemberg

The institution of school physicians has been extended throughout Würtemberg by a new law. The superior medical officer (*Oberamtsarzt*) is to be court physician, vaccinator and school physician. He will be charged with the care of the health of the pupils as a principal part of his duties. The school physician must at least once a year visit every school during the instruction period alternately in the summer and winter sessions. He must report on the grounds and the plan for new buildings and for changes in school buildings, as well as the oversight and use of these buildings and their apparatus with reference to their sanitary conditions, attend to the position of the school desks and arrange for seating the pupils according to height and capacity for hearing and seeing, as well as for the position of the body, and supervise the cleanliness of the pupils, carry out sanitary requirements in the instruction, secure a hygienic arrangement of the course of study and test the character of the materials for instruction as well. During the first year he must examine all newcomers and record his findings on a health card supplied for each child. The card contains a personal record of the child and questions to the parents with regard to previous illness. The health cards have a uniform form for the entire country.

The examination of pupils includes the general physical condition, the nervous system, the condition of the ears, eyes, nose and mouth, the chest and its contents, the skeleton, especially the vertebrae, and the limbs. Examinations which require the removal of clothing may not be undertaken in the case of girls, if any objection is raised by those responsible for their education. In any case, a female teacher must be present at such examinations. The examination may be omitted if a card properly filled by a licensed physician is presented at the right time. A similar examination must take place in the fourth and seventh or eighth school years, and also in all schools for boys before the final examination. In the later examinations, the extent of development of the body during the school period must be determined. Suitable advice as to the choice of trade must be attached to the certificates of all children dismissed from school who do not seem entirely healthy. Pupils with pathologic changes must be examined oftener. The parents must be given a statement of the findings. Treatment is not afforded, but in case the pupil is needy, report is made to the authorities. The health cards are kept until the twenty-fourth year. In the schools for technical training there is no supervision by a medical school inspector as a rule. In the normal schools, kindergartens, etc., only an inspection of the schoolrooms and the pupils, without a thorough personal examination.

In Würtemberg there are sixty-four superior districts with about 350,000 children who would be examined by the school physician. The Würtemberg government contemplates in time making the superior medical officers full-time officers and for this purpose to put two superior districts into one. Then each school physician would have about 11,000 children to examine.

Disinfection of Railway Cars

In Potsdam there is an installation for the disinfection of railway cars which so far as I know has not its equal anywhere else. A second institution of the kind is being built at Frankfort-on-the-Main. The principal feature of the entire arrangement is an iron tunnel more than 23 meters (70 feet) long and 5 meters (16 feet) in diameter. It is reenforced with fourteen rings about 6 feet apart. Two iron doors close the tunnel, one of which is fast and the other movable. The front movable door easily slides aside and then the car which is to be cleansed is run on rails into the tunnel. Board runways on the sides of the iron walls enable the workmen to gain access to the car in order to make the necessary preparations. Tubes of various kinds open into the interior. One serves to introduce steam, and another removes air by suction. In addition there are wires for the conduction of electricity.

When the car is properly prepared, the tunnel is closed up air-tight. One man can regulate the iron door with ease. The apparatus is soon made air-tight. In the nearby power-house the pumps begin to work and draw out the air in the apparatus. When a vacuum has been produced the pressure on the door is 4,142,000 kg. At the same time the warming of the apparatus to from 50 to 60 C. (from 122 to 140 F.) is shown by the thermometer and barometer, which are introduced into the interior and which show their condition by electric indicators in the power-house. The machinist knows at every moment exactly what the temperature and pressure are in the interior of the disinfecting apparatus.

The car stands for fully five hours in the air-exhausted apparatus, which has a weight of 135,000 kg.

Heat and steam are not the only means employed. By a special process vapors of formaldehyd are generated in the interior of the car to be disinfected. So thorough are these vapors of formaldehyd that they correspond to the most exacting requirements of the imperial health office. Bacteria very tenacious of life enclosed in tubes and sunk deep into the upholstering are completely devitalized.

Two cars at a time can be thoroughly cleansed and disinfected in this apparatus. Care is taken that the foul air probably contaminated with bacteria does not reach the free air. It has to pass through a furnace where it is burned. From all parts of the empire cars are brought to Potsdam in order that they may be restored to service after a most thorough cleansing. Such a cleansing costs only $5 (20 marks), whereas formerly $50 (200 marks) were required. The Postdam installation cost about $20,000 (80,000 marks).

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, August 15, 1913.

The Report of the Lupus Institute in Vienna

The ravages of lupus have for a considerable time caused appreciable damage to national welfare, so that the action of Professor Lang in establishing a special lupus clinic met a need which was universally felt. This pioneer of surgical treatment of lupus had the satisfaction of witnessing the excellent work done by this, his foundation, as published in the yearly reports of the institute. It has been in existence only three years, and yet 2,061 patients have been treated, as Director Jungmann states in the report for 1912. This figure includes about 15 per cent. coming from Australia, India, Egypt and the United States, for the reputation of the institute is already wide-spread. Of the patients applying for help 561 were treated by excision and cured permanently. The other chief factors of treatment were the Finsen light and the Roentgen rays. The institute has given to 605 patients Finsen treatment consisting of 211,622 single sittings. The trouble and time, apart from the expense, involved by this method is very large, and therefore the treatment by Roentgen rays is preferred in suitable cases because it acts quicker and necessitates less expenditure. Within the last few months the effects of radium were tried with excellent results. It is necessary to subject the diseased parts to prolonged exposures to the active rays, but then it is the best method of actinic treatment. Altogether, 610 patients received 11,764 treatments of radium, and 935 persons 8,060 Roentgen-rays treatments. As yet surgical treatment, in suitable cases, is still the best method for a complete and rapid cure. The institute is owned by the state, and this explains the difficulties encountered at the beginning of its existence.

The Number of Students of the Austrian Universities in the Summer Term, 1913

The last (summer) term of the school year 1912-1913 has again brought an increase in the numbers of students attending the lectures of the universities. Altogether 27,299 students matriculated, which is an increase of 2.8 per cent. over the corresponding period last year. The increase in 1912 over 1911 had been 5 per cent. In the year 1913, 8.2 per cent. of the total number of matriculated students were women, their number having grown 5.5 per cent. Of the sum total, 21 per cent were medical students, among them 410 women. It is interesting to note that the proportion of medical students among women is about equal to the figures for men—20 per cent. As regards the promotion or graduation of students in the last year (1912-1913), 300 candidates received their diplomas of M.D., among them sixteen women, as compared with 2,571 (ten women) in the previous year. For comparison it may be stated that the number of candidates graduating as doctors of the law was 457 in 1911-1912, while this year it was only 381. Of the medical students, 3,780 were German speaking and 2,000 belonged to other (mostly Slavic) nationalities. The religious relations are also interesting. While the Jews form only a small proportion of the entire population of this country (about 4 per cent.), they claim no less than 25 per cent. of the total number of students, especially in medicine and jurisprudence. This indicates that their desire for higher intellectual development is at least six times as great as that of the bulk of the population. It explains also why in various parts of the country the so-called "intellectual proletarians" are so evident. Hitherto, all the warnings against the overcrowding in this profession have been fruitless, and the constant influx of students to the medical career tends to produce really a crisis. The only reason that it has not yet arrived is found in the fact that in the last few years the financial footing of those young men who take up our art for their study seems to be better than in previous years. Medicine is no longer the goal of the penniless youth who thought he could make a living at the very outset of his work.

The Leading Points in the New "Epidemic Act"

A few months ago the new bill called an "Act for Prevention and Fighting of Communicable Diseases" passed both houses of our legislature and therefore is now a promulgated law. All medical men in the empire have now received instructions regarding this law in the shape of a leaflet which contained the following interesting items: "Notice of disease must be made in case of scarlet fever, diphtheria, abdominal typhus, dysentery, epidemic meningitis, puerperal sepsis, exanthematic typhus, small-pox, cholera, plague, relapsing fever, lepra, trachoma, yellow fever, anthrax, malleus and rabies, including injuries by animals suspected of being infected by rabies." (It is interesting that measles, chicken-pox and whooping-cough are not in the list. The reason given for it, that the danger of contagiousness is slight in such cases and that prevention is hardly possible, is not shared by a good many practitioners.) "Each case of disease mentioned before and each death from such as well as every case suspected of belonging to one of these diseases as well as every suspicious death must be notified to the head of the local administrative body. Only puerperal sepsis need not be notified before a definite diagnosis is arrived at. The notification must be made by the medical attendant or the head of the respective hospital or the midwife, the nurse, the head of a school, the innkeeper and, in case of anthrax, malleus and rabies, also the veterinary surgeons, if they learn from their occupation that a person has fallen ill or is suspected of being infected, suspicious objects and localities or those proved of being infectious must be disinfected, and can be destroyed if the disinfection is more expensive than their present value. The local board of health must be notified when the disinfection is completed. Damages sustained by the owners of such disinfected or destroyed objects will be paid for by the state. If persons are kept away from earning their living by being detained or quarantined, they will obtain compensation from the state. Only such persons are entitled to this compensation who are not bound to pay an income tax. The violation of the new law will be punished either by a fine of $20 (100 kronen) or from one to eight days prison. Officers of the board of public health are entitled to examine the patient or the dead body in order to ascertain the disease or the cause of death. The medical attendant must be consulted by them also. If there is a suspicion that an infectious case is kept secret, the help of the police may be obtained by the board of health." It was not possible to obtain from parliament payment of fees for such notifications for the practitioners; but the government will pay $10,000 (50.000 kronen) a year to the medical societies for orphans and widows of practitioners in recognition of the services rendered by the profession to the state.

Organization of Deaf-Mutes in Austria

Last week the tenth meeting of the Austria Union of Deaf-Mutes took place here and some important decisions have been arrived at. An association comprising all deaf-mutes of this empire was founded and the following resolutions will be brought into force by it: first of all, a sufficient number of schools for deaf-mute children shall be erected, so that all such children who are capable of learning will find opportunities for mental development. At present, no more than from about 30 to 40 per cent. of such defective individuals can be cared for in our schools. It was decided that the time of teaching should be extended to eight years instead of the present four to six years, and that the instruction should approach in its aims very near the mark required for normal children. Defectives who are not fit for schools shall be looked after in special institutions, and homes for old or invalidated deaf-mutes who have no one to care for them will also be established. Two important and interesting points of the transactions were the adoption of a uniform "finger-language" (French method) for Austria, and the compilation of a "register" comprising all deaf-mutes in this country. The uniform "language" is most necessary in our empire since there are no less than eight different nations united for mutual help; for this purpose, cooperation with the teachers of the existing deaf-mute schools will have to be effected, for in Austria the German or "oral" method of teaching is prevalent. The necessity of a register is evident for statistical and biologic reasons, and will be also of a high scientific value.

Marriages

W. H. Hombach, M.D., Omaha, Neb, to Miss Margaret Lenora Pierce of Council Bluffs, Ia., in Colorado Springs, August 7.

Ralph C. Tilley, M.D., Petersburg, Ky., to Mrs. Mattie Bradley Sparks Licker of Aurora, Ind., at Cincinnati, August 22.

Byron Porter Walker, M.D., West Monterey, Pa., to Miss Dorcas Neal Johnston of Pittsburgh, Pa., August 26.

Paul Carleton Colegrove, M.D., Iowa City, Iowa, to Miss Mildred A. Kerlin of Storm Lake, Iowa, June 11.

James Harvey Black, M.D., Dallas, Tex., to Miss Alleen Marie Patton of Catlettsburg, Ky., September 4.

Leo Paul Van Rie, M.D., Mishawaka, Ind., to Miss Lillian Oschulsky of Chicago, at Mishawaka, August 19.

Charles Schram, M.D., New York City, to Miss Anna Levi of Cincinnati, at Zurich, Switzerland, recently.

Everett Woods Maechtle, M.D., West Allis, Wis., to Miss Velma Vinal of Appleton, Wis., August 20.

Edmund Simpson Boice, M.D., Richmond, Va., to Miss Lyall E. Caughy of Baltimore, August 20.

Rev. Samuel Lichner, M.D., Chicago, to Mathilda Osborne, M.D., of Philadelphia, August 20.

Frank P. Gaunt, M.D., Nanking, China, to Miss Eugenia Moore of Macon, Mo., August 19.

Francis Roman Wise, M.D., to Miss Rupp, both of York. Pa., in Harrisburg, August 18.

J. S. Bardin, M.D., to Miss Worthie Bell Putman, both of Fort Worth, Tex., August 6.

George Buol, M.D., Ravenna, Neb., to Miss Urilla Rudy of Lincoln, Neb., August 8.

John Lick Groh, M.D., Faxman, Pa., to Miss Blanche Myers of Everett, Pa., recently.

E. R. Arn, M.D., to Miss Minna Marie Wannagat, both of Dayton, Ohio, August 27.

Deaths

Eugene Fauntleroy Cordell, M.D. for many years Maryland correspondent of The Journal, died in Baltimore, August 27, a week after an operation for abscess of the rectum; aged 70. He was born in Charlestown, W. Va., received his preliminary education in the Charlestown Academy and the Episcopal High School of Virginia. He then entered the University of Maryland, Baltimore, and was graduated from its school of medicine in 1868. For many years he was a member of the faculty of his alma mater as professor and honorary professor of history of medicine. He was also librarian of the School of Medicine of the University, and editor of "Old Maryland." His society membership included the American Medical Association; the Medical and Chirurgical Faculty of Maryland, of which he was president in 1904; the Literary and Historical Society of the University of Maryland, of which he was once president; the General Alumni Association of the University of Maryland, of which he was secretary for many years; the Johns Hopkins Hospital Historical Club, the Association of American Medical Librarians and other scientific societies. From 1896 to 1904 he was also professor of the principles of the practice of medicine in the Women's Medical College, Baltimore. In the death of Dr. Cordell the United States has lost one of its foremost medical historians, Maryland, a savant devoted to historical research, and The Journal of the American Medical Association a most faithful and competent correspondent.

Duff W. Greene, M.D. Medical College of Ohio, Cincinnati, 1876; of Dayton, Ohio; a fellow of the American Medical Association; a specialist on diseases of the eye; a member of the Medical Staff of the National Military Home, Dayton, for 29 years, and for 27 years chief of the ophthalmologic staff of St. Elizabeth's Hospital, Dayton; died suddenly in his automobile, August 16, from heart disease, aged 62.

John Crannell Minor, M.D. College of Physicians and Surgeons, New York City, 1865; a member of the French Medical and Surgical Society and a fellow of the Royal College of Physicians and Surgeons, who served throughout the Civil War as medical cadet, assistant surgeon and surgeon; died at the home of his nephew at Waterford, Conn., August 16, from cerebral hemorrhage, aged 69.

Frederick Llewellyn Bartlett, M.D. Homeopathic Medical College of Missouri, St. Louis, 1868; for 61 years a resident of Aurora, Ill., and once mayor of that city; for ten years a member of the board of directors of the Public Library and for three years its president, and for eighteen years president of the board of education of West Aurora; died at his home August 7, from uremia, aged 69.

Edwin Motley Fuller, M.D. Medical School of Maine, Brunswick, 1873; a fellow of the American Medical Association, and once president of the Maine Medical Association; for twenty years a member of the Medical Corps of the National Guard of the state and prominent in civil affairs; died at his home in Bath, August 8, from septicemia, aged 63.

Emily H. Wells, M.D. Women's Medical College of the New York Infirmary for Women and Children, New York City, 1873; a member of the Medical Society of the State of New York, and at one time president of the Broome County Medical Association; died at her home in Binghamton, August 20, from heart disease, aged 72.

Christian Van der Veen, M.D. University of Michigan, Ann Arbor. 1898; of Grand Rapids, Mich.; a member of the Michigan State Medical Society; once president of the Grand Rapids Academy of Medicine; secretary of the staff of the Butterworth Hospital; died in the Inez Mosher Hospital, August 10, from erysipelas, aged 40.

William Albert Davis, M.D. University of Pennsylvania, Philadelphia, 1876; a fellow of the American Medical Association; physician-in-chief to the Cooper Hospital at Camden, N. J., and consulting physician and director of the Camden City Dispensary; died suddenly at his home, August 17, from heart disease, aged 63.

Cleveland Ferris, M.D. Yale University, New Haven, 1903; a fellow of the American Medical Association and the New York Academy of Medicine; assistant genito-urinary surgeon to the New York Polyclinic and outpatient department of St. Luke's Hospital, died at his home at New York City, August 21, aged 36.

Robert P. Hunter, M.D. Jefferson Medical College, 1869; a member of the Medical Society of the State of Pennsylvania; a veteran of the Civil War; a member of the Pennsylvania legislature in 1911 and 1912, and a school director of Leechburg, Pa., was found dead in his bed in that place, August 13, aged 77.

H. Clay Hart, M.D. Philadelphia University of Medicine and Surgery, 1869; a veteran of the Civil War; at one time a member of the city council of Spencerville, Ohio, and a member of the school board; died at his home near Southworth, Ohio, August 11, from carcinoma of the face, aged 72.

Augustus Maverick, M.D. University of Pennsylvania, Philadelphia, 1907; a fellow of the American Medical Association; a prominent young practitioner of San Antonio, Texas; was shot and killed at his home, August 18, while endeavoring to protect one of his servants from assault, aged 28.

William B. Hostetler, M.D. Albany (N. Y.) Medical College, 1865; a member of the Illinois State Medical Society; for many years local surgeon of the Wabash system in Decatur, where he had practiced for forty-six years; died at his home, August 21, from heart disease, aged 70.

Hubbard Winslow Mitchell, M.D. College of Physicians and Surgeons, New York City, 1886; a surgeon in the navy during the Civil War; a member of the staff of Bellevue Hospital and consulting physician to Roosevelt Hospital, New York City; died at his home, August 12, aged 70.

Emma Therun Pettingill Allen, M.D. New York Medical College and Hospital for Women, New York City, 1892; a member of the visiting staff of the Brooklyn Memorial Hospital for Women; died at her home in Brooklyn, August 9, from malignant disease, aged 68.

John William Fielder, M.D. Medical College of Alabama, Mobile, 1905; of Benton, Ala.; a member of the Medical Association of the State of Alabama; died in a sanatorium in Selma, Ala., August 14, from the effects of strychnin self-administered, aged 30.

William C. Gayley, M.D. University of Pennsylvania, Philadelphia, 1881; a fellow of the American Medical Association, and a member of the Board of Trustees of the Hazleton (Pa.) State Hospital; died suddenly at his home in Hazleton, August 16, aged 54.

John G. Huck, M.D. College of Physicians and Surgeons, Baltimore, 1882; a fellow of the American Medical Association, and a well-known practitioner of Northwest Baltimore; died in Johns Hopkins Hospital, August 13, from heart disease, aged 63.

Allan Blair Bonar, M.D. College of Physicians and Surgeons, New York City, 1890; of Memphis, Tenn.; while on a visit to his mother at Detroit, died in Grace Hospital, August 14, from disease of the liver due to malaria, aged 50.

Matthew Moore Butler, M.D. Jefferson Medical College, 1860; assistant surgeon and surgeon of the Thirty-Seventh Virginia Infantry, C. S. A., during the Civil War; died at his home in Bristol, Tenn., August 12, aged 75.

Peter Herman Muus, M.D. Minneapolis College of Physicians and Surgeons, 1901; in 1905 mayor of Kensington, Minn., and later a practitioner of Albert Lea; died at his home August 12, aged 39.

Charles M. H. Schwartz, M.D. University of Iowa, Iowa City, 1880; formerly of Lyons, Iowa; died at the home of his daughter at Mooseman, Canada, August 10, from cerebral hemorrhage, aged 64.

Abraham P. Frick, M.D. University of Pennsylvania, Philadelphia, 1861; local surgeon at Aransas Pass, Texas, for the San Antonio and Aransas Pass Railroad; died at his home, July 11.

George Dutton Ladd, M.D. Rush Medical College, 1875; a member of the Wisconsin State Medical Society, and president in 1890; died at his home in Milwaukee, August 15, aged 63.

Jeromus Rapelye (license, New York), a practitioner since 1864; a veteran of the Civil War; died at his home at Maspeth, N. Y., August 12, from senile gangrene, aged 78.

Theodore Wigand, M.D. University of Marburg, Germany, 1873; a practitioner of California since 1877; was killed in San Francisco August 12, in an automobile accident.

William J. Clontz, M.D. Vanderbilt University, Nashville, Tenn., 1887; of Alexander, N. C.; was shot and almost instantly killed in that place August 11, aged 58.

Giles Harris, M.D. Kentucky School of Medicine, Louisville, 1880; died at his home in Richmond, Ky., August 10, aged 68.

Frank Walton, M.D. Vanderbilt University, Nashville, Tenn., 1899; a fellow of the American Medical Association; was shot and killed at Mulga, Ala., August 18, aged 38.

Joseph F. Blount (license, Indiana, 1897), for many years a practitioner of Evansville, Ind.; died at his home in that city, August 16, from senile debility, aged 86.

Edward G. Forshee, M.D. Cincinnati College of Medicine and Surgery, 1864; died in his home at Kinmundy, Ill., July 10, from acute gastritis, aged 78.

Charles Wilbor Ray, M.D. Bennett Medical College, Chicago, 1885; formerly of Nicollet, Minn.; died at his home in Los Angeles, August 12, aged 57.

Lewis J. Burch, M.D. Atlanta College of Physicians and Surgeons, 1904; of Waycross, Ga.; died in a sanatorium in Atlanta, August 2.

Thomas Wilson Monroe (license, Massachusetts, years of practice), died at his home in Milford, July 10; aged 68.

William Ely Jones, M.D. Miami Medical College, Cincinnati, 1890; died at his home in Cincinnati, August 11, aged 44.

Correspondence

Tuberculosis Acquired through Ritual Circumcision

To the Editor:—My attention has been drawn to an article with this title in THE JOURNAL, July 12, 1913, p. 99, by Dr. E. Emmett Holt. He concludes his article thus: "While the number of reported instances of tuberculosis acquired through circumcision is considerable, there must be a very much larger number that have never found their way into literature. It is certain also that syphilis has been spread in this manner. These facts lead me to emphasize the statement made by the late Professor Maas, the German surgeon, that 'it is the duty of the physician to raise his protest against the performance of ritualistic circumcision in every case.'"

I assume that Dr. Holt does not thus protest against all circumcision, for every physician recognizes its desirability and its necessity in his practice. And I assume that he does not protest against its being regarded by us as a religious duty, for a religion which inculcates physical as well as spiritual health must command the respect and admiration of all men. I assume therefore, that Dr. Holt objects merely to certain details of the operation as performed by some practitioners. In this he is correct.

The operation itself, as practiced, consists of three details:

1. The "Milah" or excision. For this modern surgery demands that the instrument used shall be properly sterilized before the operation.
2. The "Periah" or separation of the inner lining of the prepuce from the glans. For this modern surgery demands that a proper forceps shall be substituted for the fingers or thumb.
3. The "Metsitsa" or suction of the blood from the wound. For this modern surgery demands that a hemostat shall, when necessary, be employed to replace such a method of hemostasis.

The operation antedates by many centuries, indeed, by thousands of years, modern surgical methods. Less than a single century ago, hemostasis by hot oil or hot pitch was countenanced by accepted surgery. It required time to bring about changes to modern methods. Much less time will be required to improve the methods complained of in "ritualistic" circumcision, particularly when we remember not only that many Jewish operators in America use modern methods of asepsis, and that in such countries as England, France, Germany and Scandinavia they may not otherwise practice, but also that the Jewish religious law insists on every precaution in matters of health and demands that when "Sekanah" or "danger" to health is critically involved, any religious custom and any duty not may, but must, be overridden.

We must further remember that all the offending operators are from Russia, Roumania, Hungary, Galicia, etc., where universities and medical schools close their doors to Hebrews or receive but very few; where cruel prejudices further shackle them; where unjust laws impose further restrictions, and where, for that matter, general medical and surgical practice is in the hands of "felchers" or imperfectly trained barbers.

A few operators may demur at changes, for old customs die hard. But the operators, as a body, are open to reason and will be found obedient to all requirements, especially when told authoritatively by their religious leaders that their present methods have in them elements of "Sekanah" or "danger." I can imagine nothing that would fill them with greater horror or with more genuine sorrow than to know that they endanger life.

Some time ago, as president of the Union of Orthodox Jewish Congregations, I appointed a committee on this very matter, and subsequently I drew the attention of this local branch of the American Jewish Committee to the subject. Dr. Holt's article will spur both committees to further action.

H. Pereira Mendes, M.D., New York.
Minister Spanish and Portuguese Congregation.

Need for Inexpensive Obstetric Nurses

To the Editor:—Dr. Milligan's letter on this subject (The Journal A. M. A., Aug. 23, 1913, p. 617) treats of a matter that is of tremendous importance in St. Louis, as well as in Detroit. He bewails the fact that there is not a supply of clean, sensible, practical nurses whose services may be had by the family of small means. We have nurses of this kind, but they are failures because they belong to one of the two following classes:

Class 1 consists of women who, after helping in twenty or more cases, feel confident of their ability to manage an obstetric case without the guiding hand of a physician. Some of these women are honest. Their chief defect is that they are not aware of the extent of their ignorance. Some are not so honest, produce abortions occasionally, and make a miserable failure of their avocation. This is the class that injures the reputation of all practical nurses. Most women of this class have had no hospital training.

Class 2 consists of clean and willing workers who are aware of the deficiencies of their training and who attempt to make up for this deficiency by blindly and loyally abiding by the instructions of the physicians. A woman of this class is always busy, and as the supply does not equal the demand, she is soon justified in increasing her charges. Most women of this class are no longer very youthful and have had some hospital training. Strictly speaking, these women are not failures, but they are classed as failures here, because they are no longer to be had by the family of small income.

The poor man has a right to expect physicians' services at reduced rates. He cannot, however, make a similar claim against the graduate nurse, because she is already miserably underpaid.

I agree, therefore, that a supply of nurses who have had six months' training in a few essentials would place a poor man's wife in a safer position.

W. C. Gayler, M.D., St. Louis.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

GELATIN MOUNTING AND PRESERVATION OF GROSS SPECIMENS

To the Editor:—Will you kindly publish reference or give brief description of latest and best technic for gelatin mounting and preservation of gross specimens?

E. W.

Answer.—In the issue of The Journal for May 17, 1913, p. 1586, is given a method for preserving gross specimens in a sugar solution. The tissue is immersed in the usual formaldehyd solution for from six to twelve hours, then in 50 per cent. alcohol from twelve to twenty-four hours and then it is transferred to an oversaturated solution of beet-sugar. Only enough water is added to dissolve some of the sugar, leaving a little sugar in the bottom of the jar. That is a permanent mount.

In 1902 W. H. Watters of Boston published a method of molding specimens in gelatin. The specimen was fixed for from two to four days in Kaiserling No. 1, then from three to five days in Kaiserling No. 3, and then it was embedded in the following mixture: Kaiserling No. 3, 15 parts; gelatin, 1 part. This mixture is rendered liquid in a hot-water bath. To this is added the white of one egg and the mixture is heated until coagulation of the albumin is complete. The solution is then carefully filtered and allowed to cool. It is now ready for use. Specimens prepared in the usual way for Kaiserling solutions are cut into sections of about 1 cm. thickness in such a manner that one of the flat surfaces shows the features desired. Into a Petri dish is poured a thin layer of the gelatin solution now cooled to from about 30 to 35 C. (from 86 to 95 F.), and in this the section is placed face downward. The gelatin soon solidifies and thus holds firmly and evenly against the glass the particular surface desired to be seen. The entire Petri dish is now filled with gelatin solution till a convexity is formed above the edges. A square glass plate is removed from a basin of water and placed, while still wet and with the rough surface down, over the Petri. If this procedure is performed carefully, touching first one edge of the dish with the plate and then dropping it slowly, a wave of gelatin will be formed which will force out any air bubbles that may be present. The plate is placed in proper position and the entire preparation left to harden, which it will do quite well in from half an hour to two hours, according to its initial temperature and the degree of room heat. After the superfluous gelatin has become solid it is removed by a coarse brush immersed in water. The glass is then dried, a layer of Canada balsam is applied to seal the point of union between the plate, which we now recognize as the base, and the Petri dish, which now forms the top of the mount, and the name of the specimen is written in ink on the ground glass. In a day or two the balsam will be dry and the preparation has been completed.

BLOOD-PRESSURE AND THE EFFECT OF ALTITUDE

To the Editor:—1. What is considered normal blood-pressure in man?

2. What is the effect of altitude on blood-pressure? Does an altitude of 7,000 feet make any difference in blood-pressure?

G. W. Linville, M.D., Woodmen, Colo.

Answer.—1. The normal blood-pressure may be stated as an average of 127 for males, all ages, and 120 for females. There are many circumstances which cause a variation from the average. The blood-pressure tends to rise with age, so that a pressure considerably above the average at the age of 60 might not be abnormal.

2. The blood-pressure is diminished with altitude, the difference at 6,000 feet being about 5 mm.; but long residence at high altitude tends to make it return to nearly the normal figures. The fall of systolic pressure is slightly greater and more certain to occur than the fall of diastolic pressure. High altitudes do not affect all persons in the same degree, and small elevations in altitude do not materially influence blood-pressure.

Reference may be made to the work of Charles F. Gardiner, M.D., and Henry W. Hoagland, M.D. (*Tr. Am. Climatol. Assn.*, 1905, xxi, 80); and those of Y. Henderson (*ibid.*, xxviii), and of W. A. Campbell, (*ibid.*, xxviii, 16).

RELATIVE THERAPEUTIC VALUE OF SALVARSAN AND NEOSALVARSAN

To the Editor:—Please answer the following questions with reference to salvarsan and neosalvarsan:

1. Which is the least toxic?
2. Which gives the better results (therapeutically)?
3. Which is the better preparation (*a*) for intramuscular work; (*b*) for intravenous?
4. Being away from a laboratory doing the Wassermann, as a general rule how many doses would be considered sufficient, the patient receiving the first dose during the primary or secondary stages?

J. C. M.

Answer.—1. There appears to be no essential difference.

2. The two are believed to be practically identical in their therapeutic effects. Some authors, however, who have tried both prefer salvarsan.

3. (*a*) Probably salvarsan. (*b*) Probably neosalvarsan.

4. The physician who undertakes the treatment of a case of syphilis should be prepared either to perform the Wassermann test himself or to have it done at a laboratory. Specimens of blood can easily be sent for such examinations. It is impossible to state positively how many injections are needed. The proper treatment of this disease requires the administration of mercury as well as salvarsan. The physician must be guided in the use of salvarsan by the condition of the patient and the character of the Wassermann reaction as to whether he shall use one or more injections of salvarsan in a series, and the number of series required, as well as the interval between them.

WALNUT JUICE AS A HAIR-DYE

To the Editor:—*Please give me the following information: 1. What is a good, harmless dye for making the hair black? 2. Is walnut stain a good, permanent dye? 3. Where can a trustworthy preparation of walnut stain be bought? 4. Is henna better, and what is a trustworthy preparation of this substance?*

ANSWER.—1. There is no hair-dye that is exactly satisfactory and none that can be guaranteed harmless under all circumstances. Analyses and published formulas of hair-dyes show that most of them contain one or more of the following substances in addition to solvents or ointment bases: salts of bismuth, copper, iron, lead, silver and vanadium, ammonium sulphid, ammonium carbonate, hydrogen dioxid (in conjunction with tinctorial substances) pyrogallol, paraphenylen diamin (and other anilin dyes), henna and walnut juice. Several of the less objectionable formulas for black hair-dyes were given in THE JOURNAL A. M. A., Oct. 14, 1911, p. 1305.

2. Authoritative information is lacking concerning the permanence of walnut juice as a hair-dye. Walnut juice alone produces a brown stain on the hair, but a darker color may be obtained by using it in conjunction with some nigrescent substance such as resorcinol or pyrogallol. The following formulas were published in the *Druggists' Circular*, August. 1907, p. 545:

	gm. or c.c.	
Green walnut hulls	40	ʒ x
Resorcinol	4	ʒ j
Glycerol	60	fl℥ ij
Water	enough	

Grate the hulls and boil in 500 c.c. or a pint of water for thirty minutes, strain, add the resorcinol, glycerol and enough water to make 400 c.c. or 14 ounces.

	gm. or c.c.	
Copper chlorid	150	℥ v
Distilled water	325	℥ xi
Stronger ammonia water ...	150	fl℥ v

Mix and add gradually. with constant stirring to a solution of:

	gm. or c.c.	
Pyrogallol	200	℥ vii
Hydrochloric acid	675	℥xxiiss
Distilled water	1,000	℥ xxxii

Then add with stirring·

	gm. or c.c.	
Stronger ammonia	190	℥ viss
Solution of hydrogen dioxid	950	℥ xxxii
Water enough to make ...	*4,000*	℥ *cxxviii*

Store in a wide-mouthed jar exposed to the air for fourteen days, stirring the liquid occasionally.

3. It is probable that most of the commercial preparations which use such expressions as "walnut stain," "walnut tint," etc., as selling points do not contain any walnut juice, but depend for their colorific properties on some of the synthetic dyes, such as paraphenylen diamin. (THE JOURNAL A. M. A., April 3, 1909, p. 1121, and Oct. 16, *1909*, p. *1307.*)

4. Henna stains the hair yellow.

LAVAGE IN CASES OF HEMORRHAGE

To the Editor:—In THE JOURNAL, July 26, 1913. p. 256, Dr. Billings states: "In hemoptysis due to chronic ulcer of the stomach, hemorrhage may not cease so long as the stomach is distended with blood and other contents. Lavage with normal salt solution, until the stomach is empty, is safe and often effective." I dislike to express a contrary opinion, but it appears to me that a statement like the above is a dangerous one to make for obvious reasons. To my mind, such advice needs some reservation or limitation.

W. F. VON ZELINSKI; Chicago.

ANSWER.—Lavage in cases of hemorrhage of the stomach is recommended by a number of authors and under the conditions indicated by Dr. Billings is fully justified. Our correspondent's opinion emphasizes the necessity of following advice with due consideration of the conditions present, and the proper caution in the manipulations necessary.

DURATION OF IMMUNITY FROM TETANUS AFTER INJECTION OF ANTITETANIC SERUM

To the Editor:—Recently a client brought to my office his son, who had stepped on a rusted nail. I advised a prophylactic injection of antitetanic serum, which was given. After the injection my client asked, "How long will my son now be protected against tetanus?" Please give me your opinion.

R. A. C.

ANSWER:—Tetanus antitoxin is *eliminated* from the system from eight to ten days after injection. It remains in practically undiminished amount for a week and then rapidly diminishes to nothing in the course of a few days. Therefore the immunity conferred is protective for not more than a week.

EPIPHANIN AND NINHYDRIN REACTIONS

To the Editor:—Please give information with regard to the following: (1) epiphanin reaction, (2) ninhydrin reaction.

C. E. McBRAYER, M.D., Haines, Alaska.

ANSWER.—1. The epiphanin reaction is applied to the detection of antibodies in the blood-serum, especially in the serodiagnosis of syphilis. The technic depends on a change of reaction to phenolphthalein in a neutralized solution. A mixture of the suspected solution and of an extract from a syphilitic organ are made as follows: 0.1 c.c. of a 10 per cent. solution of the serum in physiologic salt solution is mixed with 0.1 c.c. of an alcoholic extract of a syphilitic fetal liver. To this is slowly added 1 c.c. of decinormal sulphuric acid and 1 c.c. of an exactly equivalent solution of barium hydroxid. On the addition of a drop of phenolphthalein solution, the fluid turns red if the serum is from a syphilitic, while there is no change in tint with the serum of a non-syphilitic person. See also Abstract 74, THE JOURNAL, Jan. 21, 1911, p. 228.

2. Ninhydrin is a proprietary name for triketohydrindenhydrate, used as a reagent for proteins and amino-acids. The reagent gives a blue color with all compounds which have an amino group in the alpha position to the carboxyl. It is used for the detection of peptone or amino-acid in a test for pregnancy as follows: About 1 gm. of coagulated placental tissue, which on boiling with water yields no compounds which react with ninhydrin, is placed in a diffusion cell and covered with from 2 to 3 c.c. blood-serum and the mixture dialyzed in 20 c.c. distilled water. The contents of the cell and the outer fluid are covered with a layer of toluol. Dialysis is continued from twelve to sixteen hours at a temperature of 37 C. in the incubator. To 10 c.c. of the dialysate 2 c.c. of a 1 per cent. aqueous solution of ninhydrin are added. The mixture is heated and kept at the boiling point for just one minute. If the serum is derived from a pregnant woman, a blue coloration of the dialysate occurs. This coloration is absent if the serum is from a person who is not pregnant.

ABDERHALDEN'S SERUM DIAGNOSIS OF PREGNANCY

To the Editor:—Please give me the address of Dr. Abderhalden, the originator of the biologic test in the diagnosis of pregnancy, and directions for the preparation and administration of the test.

C. D. BOUVIER, Berkeley, Cal.

ANSWER.—Professor Emil Abderhalden, Professor of Physiology, Halle University, Halle, Germany.

Abderhalden's test for pregnancy is based on the observation that when foreign substances are introduced into the blood a specific ferment is elaborated which is capable of decomposing these materials; thus in pregnancy cells from the placenta enter the blood and excite the formation of ferments capable of digesting the placental cells. The products of this decomposition of placental cells are diffusible protein derivatives, either peptones or amino-acids. If, therefore, a piece of placental tissue is acted on by the serum of a pregnant woman, the cells of the placenta will be decomposed, and soluble and diffusible products will be formed. When such a mixture is placed in a diffusion cell the products of the digestion diffuse into the water surrounding the cell and may be detected in the dialysate. If the serum is from a non-pregnant woman, no specific ferments are present, and hence no digestion takes place and no products diffuse into the dialysate. Abderhalden employs the ninhydrin reaction for testing the presence of these protein derivatives in the dialysate. It is evidently necessary before applying this test to make sure that the material tested contains nothing which can diffuse through the membrane so as to give the reaction. Abderhalden states that it is not enough to test the placental tissue and the serum by themselves, but that a test of the two combined must be made.

The biologic test for pregnancy, according to Abderhalden, is carried out as follows: About 1 gm. of coagulated placental tissue is boiled with ten times its volume of water, the water poured off and this treatment repeated until the liquid contains nothing which will give a reaction with ninhydrin. When it no longer responds to the ninhydrin test it is placed in a diffusion cell with from 2 to 3 c.c. of blood-serum, and the mixture is allowed to diffuse into 20 c.c. of distilled water. Both the dialysate and the liquid in the cell are covered with a layer of toluol. The dialysis is continued for from twelve to sixteen hours in the incubator at a temperature of 37 C. (98.6 F.).

To 10 c.c. of the dialysate 0.2 c.c. of a 1 per cent. aqueous ninhydrin solution is added, and the test performed as follows: The mixture is placed in a test-tube and boiled for exactly one minute. If protein derivatives are present, the mixture will turn blue and it may be assumed that the serum comes from a pregnant woman. If no color appears, it is to be assumed that the serum is from a non-pregnant woman.

Abderhalden also tests for pregnancy by mixing the serum with a solution of peptone derived from the placenta. If the peptone is decomposed, a change in the optical rotatory power will occur which can be detected by examining the mixture in a special polarimeter devised by Abderhalden. This method is more expensive than the dialysis method, but is said to be more accurate.

The following is a list of references on Abderhalden's serum diagnosis of pregnancy:

THE AMERICAN HOSPITAL OF PARIS

To the Editor:—Please give a brief outline of the (1) history, (2) location, (3) resident staff, (4) facilities, (5) departments, (6) maintenance, etc., of the American Hospital of Paris.

M. Q.

ANSWER.—Write to the American Hospital of Paris, 55 Boulevard du Château, Neuilly-sur-Seine, Paris, France.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF POSTGRADUATE WORK, CONTRACT PRACTICE, LEGISLATION, MEDICAL DEFENSE, AND OTHER MEDICOLEGAL AND ECONOMIC QUESTIONS OF INTEREST TO PHYSICIANS

NEWSPAPER COMMENTS ON PUBLIC HEALTH TOPICS

Newspaper comments on public health topics are increasing both in frequency and in seriousness of consideration. A few years ago an editorial on a health topic in a daily newspaper was a curiosity, and the views of the majority of newspaper editors on this subject were too often hazy or flippant. To-day, the leading newspapers of the country recognize that the conservation of the public health is one of the most serious subjects which can be discussed in their columns. The change in public sentiment during the last six years, as reflected by the editorial columns of the leading newspapers, is most striking. Even the more radical proposals of those interested in eugenics have not failed to secure commendation from many of the big newspapers, at least so far as the spirit of the proposed regulation is concerned.

State Regulation of Marriage

The Memphis (Tenn.) *Commercial Appeal,* commenting on the passage of the radical law for the restriction of marriage in Wisconsin, says:

"Wisconsin has blazed the way . . . . Realizing the advantage of a strict marriage law, by an overwhelming majority in both branches, the legislature has passed one which will become effective on August 1. It is undoubtedly a radical move, but it is a move which will certainly be followed by other states in a very short time. The eugenic problem has been closely studied. It has grown in importance . . . The two measures enacted by the Wisconsin legislature are drastic enough to satisfy the most extreme advocate of the new cause. Both measures apply to marriage and the future of the race . . . Common sense shows the great advantage of both of these laws. Too many people, unfitted for marriage, rush into the responsibility of such an estate without realizing what the future will be. Men and women afflicted in a way which should prohibit their marriage do not profit by this knowledge and suffer afterward."

The Chicago *Record-Herald* is in sympathy with the movement, but sounds a warning, the keynote of which is a quotation from a British physician to the effect that the United States has "possibly gone too far" in eugenics legislation. Regarding the discussion in the different state legislatures, the *Record-Herald* looks on some of it as experimental, some as sensible and simple and some as perhaps unduly in advance of true scientific knowledge:

"The marriage certificate is an excellent safeguard within reason. To demand perfect health, instead of freedom from certain diseases, is to encourage immorality and to make our last state worse than the first. The business of students of eugenics is quite as much to tell legislators what not to attempt at this stage as it is to tell them what restrictions social health and social purity render it imperative or at least proper to impose."

The State's Duty in Public Health

The Cincinnati *Enquirer* discusses the relation of the state to health in a broad way, saying:

"It is coming to be taken for granted that as the state is charged with the duty not only of punishing crime, but also of preventing it, so it is also its duty not only to care for all sufferers from disease who are unable to care for themselves, but to use every possible means which modern scientific knowledge has made available to prevent disease."

After discussing governmental quarantine regulations, old-age pensions and industrial insurance in the light of this general belief, the *Enquirer* sees no reason why the state is not justified in securing better hygienic and social conditions in regulating or at least restricting the production of future generations, it says:

"Both lawyers and doctors have been studying the question of the sterilization of idiots, feeble-minded persons, and some classes of criminals, with a view to eliminating them eventually from the social fabric. The doctors, as a whole, have not acted in the matter, although their journals seem favorable to such a law. The lawyers have had a committee report on the subject, which makes no recommendation . . . If the state is justified in entering every man's domicile and insisting that he send his children to school, surely it is of equal or even greater concern to the good of all, both now and for generations to come, that it sees to it that good health is

Book Notices

A System of Treatment. By Many Writers. Edited by Arthur Latham, M.A., M.D. (Oxon.), F.R.C.P. (Lond.), Physician and Lecturer on Medicine, St. George's Hospital, and T. Crisp English, M.C., B.S., F.R.C.S., Senior Assistant Surgeon and Lecturer on Practical Surgery, St. George's Hospital. Vol. I, General Medicine and Surgery. Pp. 1352. Vol. II, General Medicine and Surgery. Pp. 1335. Vol. III, Special Subjects. Pp. 1194. Vol. IV, Obstetrics and Gynecology. Pp. 883. Many illustrations. Cloth. Price, $24 net. New York: Macmillan Company, 1912.

This is a work of almost encyclopedic dimensions, covering the entire ground of medicine and surgery by means of short articles by various authors. Such works are subject to limitations which make a general review very difficult, and a critical judgment must be founded on a thorough and detailed consideration of the entire work. The feature that perhaps is most striking is the brief space necessarily allotted to some seemingly important subjects. Thus the subject of congenital affections of the heart is dismissed with a dozen lines in which must be said that which is to guide the practitioner in dealing with what may be very difficult cases. It would seem that such space might be spared to other topics and the reader referred to text-books which will give him the necessary information as to diagnosis and symptomatology as well as treatment. Another point which must be noted is the attitude toward proprietaries and the readiness with which claims of doubtful validity are accepted by some of the contributors. An unfavorable impression is created by the article on typhoid fever. The following paragraph will probably be instructive to many of the younger American physicians who perhaps have never heard of the method of treatment described, but which is not mentioned in up-to-date American text-books. To others it will sound like an extract from a pamphlet of the previous generation.

> "The Woodbridge Treatment.—This has been introduced in America and is much vaunted. The idea is to produce early in the disease a marked cholagogue, laxative and antiseptic effect by the use in small doses continuously repeated of podophyllin, calomel, guaiacol carbonate, menthol and eucalyptol, followed on the third or fourth day of the disease by the antiseptics and antipyretics guaiacol, menthol and eucalyptol only, with occasional use of the cholagogues. The prescriptions are made into tablets by Parke, Davis & Co., and sold with Woodbridge's directions."

The author seems to think as highly of this treatment as any other. If we take this as a sample of the modern point of view of the work we should perhaps do an injustice. In the treatment of auto-intoxication, however, we find no mention of diet or of the lactic acid bacilli as effective in such cases.

The authors of the various sections are evidently not troubled by any scruples as to the recommendation of proprietary remedies, and the zeal with which this liberty is used is sometimes startling. We have become accustomed to regard it as a blemish on American medical literature that some of our second-class journals permitted the recommendation of a number of nostrums, and it has been thought a proper subject of ridicule to quote examples of their indiscriminate mention. What better example could be cited than the following from W. Soltau Fenwick, who, in the treatment of achylia gastrica, says, "Pepsin, Pepsencia, Lactopeptin or the Peptenzyme Tablets may be prescribed." He says nothing of the necessity of accompanying them by hydrochloric acid. Again, in treating atony of the stomach he informs us without a hint of doubt that "the tabloids of Peptenzyme, which consist of a mixture of all the digestive glands, are occasionally of use."

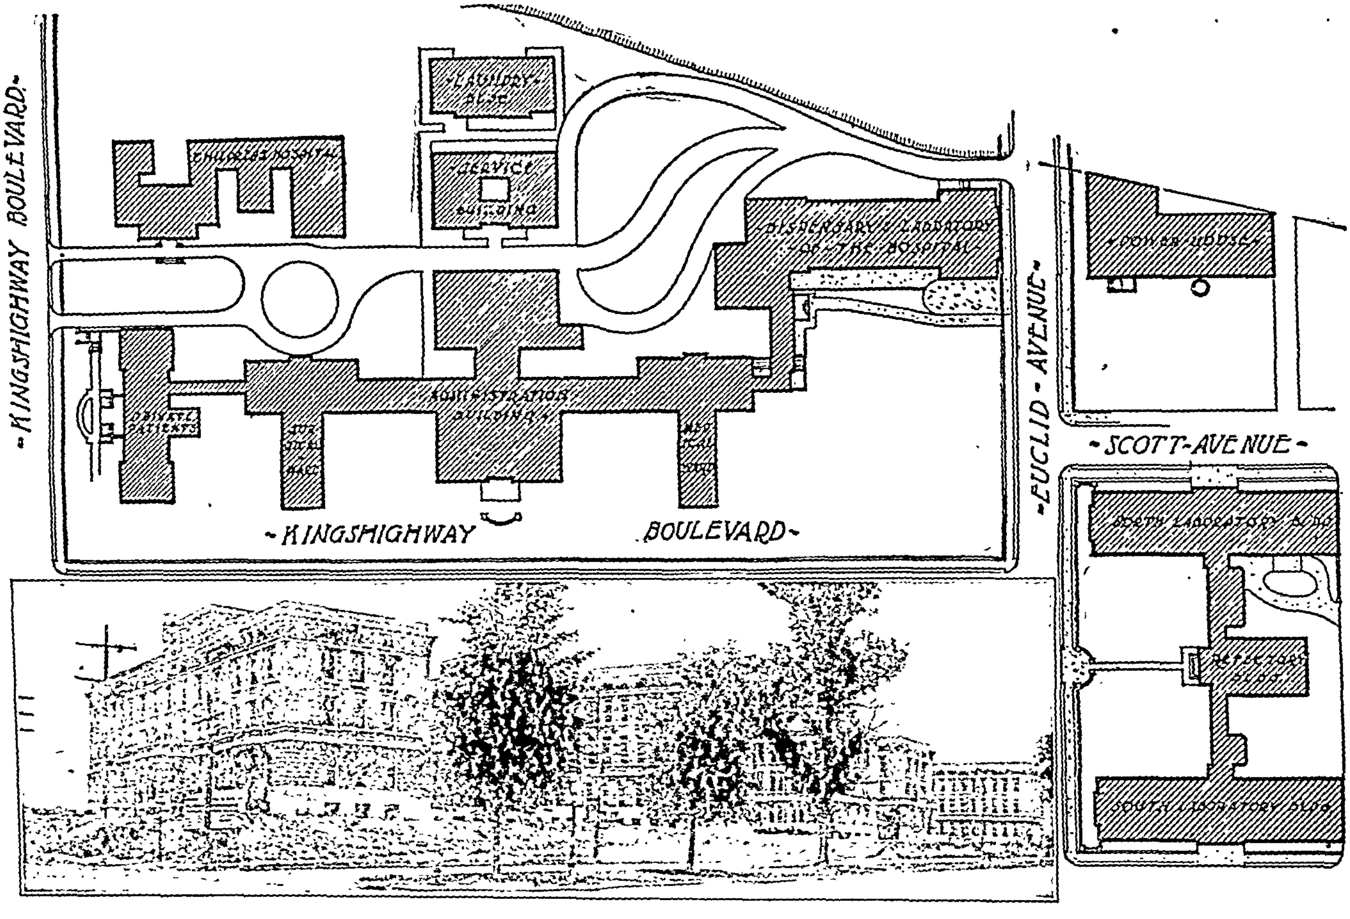
Aside from the faults mentioned and some minor errors, the treatment in general is judicious and will meet the needs of the practitioner for whom it is designed. In the treatment of enuresis by Leonard Williams, thyroid extract in small doses is recommended. The author speaks further of the use by Zanoni and Ferari of suprarenal extract in doses of from 20 to 30 drops of a preparation which he says is not specified. Such an indefinite statement will be very puzzling to the reader who wishes to use this drug. Experiment with other organ extracts is recommended in cases which resist thyroid before resorting to atropin. Another example of recommendation of an indefinite remedy which may turn out to be a nostrum is the notice given to "Lactoserum" in arteriosclerosis. Such a serum is presumably produced by injecting an animal with milk, but the article gives no details as to what animal is used or what technic is followed. A considerable section is devoted to diseases and injuries of the esophagus, but the dilatation of the esophagus as the result of cardiospasm seems to have completely escaped the author's attention. The serum treatment of hemophilia is rather summarily dismissed on the ground that the danger of bleeding from the injection wound contra-indicates it. The articles on genito-urinary affections are thorough, and there are a number of terse summaries which enable the reader to gain a clear impression of the whole subject. In general the description of surgical treatment is good and is well illustrated. The fourth volume is devoted to obstetrics and seems to give the practical help which the practitioner needs. On the whole, we must conclude that the series constitutes a useful work, but we wish that it could have been better. It is a serious question whether a divorce of treatment from other departments of medicine is possible without sacrificing the proper point of view. Must not pathogenesis, symptomatology and etiology determine the treatment, and is it not true that the same name may cover different affections the treatment of which must be different? If this is true it seems that a careful condensation could give us in the same space a treatise on medicine in its entirety which would better meet the needs of the modern physician than the present or any other disconnected exposition of treatment alone.

The Modern Treatment of Nervous and Mental Diseases. By American and British Authors. Edited by William A. White, M.D., Superintendent of the Government Hospital for the Insane, Washington, D. C., and Smith Ely Jelliffe, A.M., M.D., Ph.D., Adjunct Professor of Diseases of the Mind and Nervous System in the Post-Graduate Medical School and Hospital, New York. Volumes I and II. Cloth. Price, $6 net per volume. Philadelphia: Lea & Febiger, 1913.

The somewhat unusual point of view from which this work regards the subject presented is deserving of attention. Instead of beginning with the physical as primary and making the psychic a mere appendage, the authors approach the diseases of the nervous system from a conception of life in which the psychic is deemed worthy of quite as much consideration as the physical. The authors think that previous writers have been too much concerned with details, such as disorders of gait, of power, of sensation and of related phenomena, to the neglect of the larger problem of the individual, the biologic unit and his social relations. "Practically all such works have stopped short where they should have begun. They have told us in large measure how to patch up broken machinery, but rarely have they ever suggested or given directions for avoiding the wrecks." The point of view is essentially therapeutic and optimistic. The attempt is made to give sufficient details so that the reader may apply the methods described with intelligence and confidence. The authors oppose the delegating of any of his functions by the physician to the clergyman or other agency. The physician alone is prepared to understand morbid phenomena, and to him is entrusted the task of correcting them. The field of mental disease is regarded as one of the most fruitful in preventive medicine, and consequently much space is given to discussing the sociologic relations of nervous and mental disease and to the influences of the social environment which tend to produce them.

The work is the result of the collaboration of a large number of contributing writers.

In carrying out their plan the authors have begun with the consideration of eugenics and heredity, and from this proceed to the treatment of sexual relations, impulses and ideas. The treatment of feeble-mindedness, and the social and legal relations of mental defect are then discussed. The psychoneuroses receive extensive treatment. The first volume contains an article of considerable length on the influence of immigration on the incidence of mental disease. In dealing with the minor psychoses the method of Freud receives a thorough description, and the method of psychanalysis especially seems to have the thorough approval of the authors. The second volume deals with disorders of the peripheral nerves, the spinal cord, syphilis of the nervous system and organic diseases of the brain. Dangerous and habit-forming drugs and the surgery of the brain and spinal cord are treated in separate chapters. The value of this work to the medical practitioner must be judged by the fact that not only is he frequently called on to treat the functional nervous affections and minor psychoses and must deal with the first stages of the graver mental disturbances, but also he frequently has occasion to give an opinion or has the opportunity to influence public opinion in regard to the medicolegal and sociologic relations of these conditions. For these purposes the work seems to be an excellent guide.



New Barnes Hospital and Medical Building, Washington University.

Miscellany

MODERN HOSPITALS

During the last year new hospitals have been erected which are to be the teaching hospitals of two medical schools. These are the Peter Bent Brigham Hospital connected with the Harvard Medical School, Boston, and the combined Barnes, Children's and University Hospitals connected with the Washington University School of Medicine at St. Louis. New college buildings are also being erected for the latter medical school. The erection of these new buildings is another evidence of the remarkable development going on in medical education to-day, and is considered of sufficient importance to deserve mention here.

The Peter Bent Brigham Hospital

Probably the latest word in hospital construction, architectural, medical and executive, is at the corner of Huntington Avenue and Francis Street, Boston, separated by a private way—Van Dyke Street—from Harvard Medical and Dental Schools, the Cancer Hospital, Children's Hospital, Infants' Hospital and the Carnegie Nutrition Laboratories. Here under the direction of Superintendent Herbert B. Howard, M.D., long known as the superintendent of the Massachusetts General Hospital, on a lot about 1,300 feet by 400 feet has grown up a group of fifteen buildings. Their arrangement connected by a three-story corridor as axis may be the result of the shape of the land but the perfection of detail everywhere evident can have come only from long study by the superintendent and his medical advisors, the trustees and the architects.

The architectural simplicity of the buildings of brick and cement construction is in marked contrast to the white marble of the buildings of Harvard Medical School close by. For this is not primarily a monument to Peter Bent Brigham but a "hospital for any indigent sick resident of Suffolk County whose disease is not contagious or chronic." For land and for the erection of the buildings $1,350,000.00 has been spent, leaving about $4,500,000.00 as a fund for the maintenance of the institution.

The diagram gives the general arrangement. Room is left for the enlargement of the nurses' home and the out-patient building, as may be needed, and for the erection of additional wards. The latter will be like Ward A with its small wards and private rooms, or like Ward C with its open wards and terrace-like structure. At one end each ward is of one story with a monitor top; the central portion is two stories with one large ward and two single rooms on each floor, and at the other end the ward is of three stories, the third story being for isolation purposes and open air treatment. This secures the maximum of light and air to every room and ward. Each of the other buildings to the north is set on a lower level and does not obstruct light or air even to the main wards. Around each ward are wide verandas. Doors everywhere are wide enough for the passage of a bed. The main doors are of heavy oak set in Braun iron frames. Others are light, easily swinging double doors which, by a touch of the foot on a catch, become ordinary doors but are automatically released.

The Administration Building with its dignified pillared front proves that architectural beauty was not forgotten even if it was not made first in the construction of the hospital. Everything centers here at the desk of the clerk in the large rotunda which resembles the desk of a first-class hotel. He is closely connected with the Administrative Department. Every one must enter by the front gate and pass under his eye. There are no steps to climb. Even a wheel chair will easily enter. The single exception is the entrance for doctors and medical students on Vandyke Street, where there is ample parking space for automobiles. But they too must pass the watchful eye of the clerk. There are no back gates or doors.

Patients therefore easily walk or are rolled through the connecting corridor to the admission room in any ward. Adjoining is a large room for the admission bath. A sterilizing closet for clothing is available in one corner. Into bed at once and rolled to the ward is the rule, for every bed is a rolling stretcher. Each bed has easy running wheels with tires of canvas and a little rubber which will not dent on standing. Two of the wheels are on swivels so that one person can control, but can be locked firmly when in the proper location. These beds are the result of long study and their success is attested by the fact that the nurse herself rolls her patient through the wide door into the open air when she wishes without calling for the aid of an orderly. A patient suspected of having a contagious disease is rolled to the elevator in any building, carried to the third story and kept in an isolation room or in the open air. If a contagious disease develops, he is taken down in the elevator still in his bed, and from the open air of the corridor removed to the contagious hospital. This secures a minimum exposure of other patients.

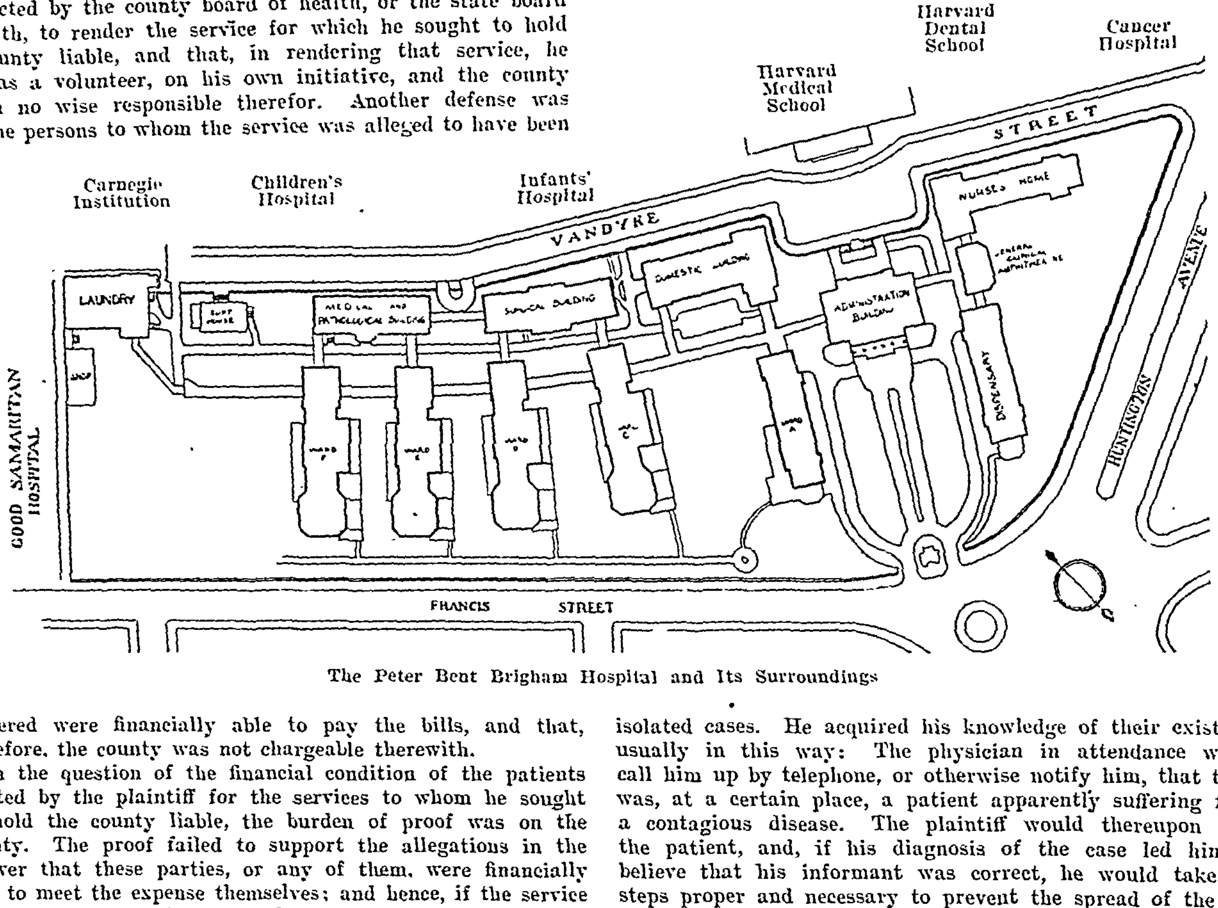
Peter Bent Brigham Hospital

The Hospitals and New Medical School of Washington University

Three years ago a gift of approximately $3,000,000 from four prominent citizens of St. Louis—William K. Bixby, Adolphus Busch, Edward Mallinkrodt and Dr. Robert S. Brookings—was announced as having been given for the development of the Washington University School of Medicine. Just previous to that time the trusteees of the Barnes estate had determined to erect a new building for the Barnes Hospital and the trustees of the Children's Hospital likewise were planning to erect a new building for that institution. Fortunately, a close affiliation of all these institutions was formed and it was determined to have a group of new buildings erected in close proximity on a tract of ground at Kingshighway and Euclid Avenue. It was recognized that the hospitals would need an attending staff of high efficiency which Washington University agreed to furnish. On the other hand, it was evident that the medical school needed to have in connection a large modern hospital. In the affiliation agreement between Barnes Hospital and Washington University the latter institution was to erect the new building at an initial cost of approximately $1,000,000, the maintenance to be met from the income of the hospital's endowment—approximately $2,000,000. Thus it was planned to have Washington University Medical School, the Washington University Hospital, the Barnes Hospital and the St. Louis Children's Hospital, formerly widely separated in different parts of St. Louis, brought together and affiliated into practically one institution centering about the Washington University School of Medicine. Plans for the new buildings were carefully prepared along strictly modern lines. The style of architecture used may be called a modified and modernized Colonial. The floors are generally of marble, tile or battle-ship linoleum; wood has been sparingly used. For the walls, marble, glass, enameled brick and tile have been freely employed, not so much as decorative features, however, as in places where sanitary reasons recommended their use. The exterior walls are constructed of an impervious gray brick on all sides, and trimmed with limestone. The cornices and copings are of limestone. The buildings are now rapidly approaching completion. The general relationship of the various structures and the appearance of the buildings when completed are shown by the accompanying cuts. This group consists of the buildings of Washington University School of Medicine, the Barnes Hospital, the St. Louis Children's Hospital and the building for Department of Pathology and the Dispensary. Two other buildings proposed are a Nurses' Home and a Maternity Hospital. All buildings, with the exception of the last two, are expected to be ready for occupancy by Jan. 1, 1914.

Thus we have another great work accomplished in the recent remarkable development of medical education in the United States. The close affiliation formed between the hospitals named and the Washington University School of Medicine are in accordance with the positive trend of the time. It is clear that the three principal functions of an ideal hospital are: (a) the best care of the sick; (b) the training of medical men for the future, and (c) the advancement of medical knowledge. No one of these functions is well performed unless all three functions are being fulfilled. The best conducted hospitals of the day are entirely those which are in close relationship with strong up-to-date medical schools. These seem to be the accepted ideals at the new Medical School of Washington University and its affiliated hospitals.



The Peter Bent Brigham Hospital and Its Surroundings

Medicolegal

Right of Health Officers to Compensation—Acting without Proper Authority

(Hickman County vs. Scarborough (Ky.), 149 S. W. R. 1116)

The Court of Appeals of Kentucky reverses a judgment recovered by Dr. Scarborough, the plaintiff, for services as health officer of Hickman County, holding that, on the showing made, a verdict should have been directed for the defendant county. The court says that the plaintiff, conceiving that his rights were fixed by an order or resolution of the fiscal court of the county fixing the compensation of the health officer, rendered services for which he sought to recover $324, but the defense was interposed that he was not ordered or directed by the county board of health, or the state board of health, to render the service for which he sought to hold the county liable, and that, in rendering that service, he acted as a volunteer, on his own initiative, and the county was in no wise responsible therefor. Another defense was that the persons to whom the service was alleged to have been rendered were financially able to pay the bills, and that, therefore, the county was not chargeable therewith.

On the question of the financial condition of the patients treated by the plaintiff for the services to whom he sought to hold the county liable, the burden of proof was on the county. The proof failed to support the allegations in the answer that these parties, or any of them, were financially able to meet the expense themselves; and hence, if the service was in fact rendered by the plaintiff in his official capacity as health officer of the county and while he was proceeding as directed by the statute, the county should be required to pay the contract price, if the order adopted by the fiscal court, and on which the plaintiff relied, was a valid and binding contract; or, if this order was invalid, then the county should be required to pay the plaintiff for such service its reasonable value.

Section 2055 of the Kentucky Statutes makes it the duty of the fiscal court to fix the compensation of the health officer by allowing to him a salary. The evident purpose and object of the legislature in passing this act was to prevent controversies between the health officer and the fiscal court growing out of questions of this character. But, as it is the plain duty of the county to meet the legitimate and proper expenses of the health officer, when he proceeds in the way and manner as by statute directed, the failure of the fiscal court, in advance of the service rendered, to fix a salary as compensation for the health officer, could not have the effect of defeating him in his effort to collect for such service the reasonable value thereof.

The serious question presented by the record was: Did the health officer act on the direction of the county board of health, or was he acting on his own initiative? The uncontradicted evidence of the plaintiff himself, as well as that of the chairman and another member of the county board of health, showed that a blanket instruction had been given him to look after the sanitary and health conditions of the county, and to take such steps as, in his judgment, were necessary to prevent the spread of contagious and infectious diseases. The record did not show just when this blanket instruction was given. There was no evidence that the record kept by the county board showed that such an instruction was given; but it was unnecessary that there should be a record to this effect. If, in fact, the county board passed such an order, it might be proved by oral evidence. There was no showing that at the time this general authority was [illegible] here was prevalent in the county any contagious dis[illegible] The services rendered by the plaintiff were in two isolated cases. He acquired his knowledge of their existence usually in this way: The physician in attendance would call him up by telephone, or otherwise notify him, that there was, at a certain place, a patient apparently suffering from a contagious disease. The plaintiff would thereupon visit the patient, and, if his diagnosis of the case led him to believe that his informant was correct, he would take the steps proper and necessary to prevent the spread of the disease. When he would thereafter meet members of the county board, he would tell of the way and manner in which he was discharging the duties of his office. On one or two occasions he met as many as two members of the county board of health, physicians, and discussed with them certain cases, which were then being treated by him, and was advised that he was proceeding with the work to the satisfaction of the board. It was apparent from the testimony of the chairman of the board of health that he regarded the law as fully complied with by issuing to the health officer a general instruction to go ahead and look after the sanitary and health conditions of the county; and hence he did not deem it necessary to call a meeting of the board to give explicit directions concerning any particular case; and this undoubtedly was the reason why the board did not meet and take action on the several cases which were treated and looked after by the plaintiff. The county board intrusted to the plaintiff the discharge of the duties which were, by Section 2055, imposed on it. On this showing the court should have directed a verdict for the county.

The county board can, when acting within the jurisdiction conferred on it by statute, bind the county. But the health officer has no such power. He is a mere ministerial officer, a creature of the board, charged and instrusted with the duty of carrying out its orders. His duties are defined and fixed by the statute, and it is only when he acts under the order and direction of the county board that the county is responsible for expenses incurred or made by him. Not only so, but he must have the authority, in each case, in advance of any action on his part looking toward establishing a quarantine, or doing any other act for which a claim is to be made against the county.

Licensed Physician Employing and Aiding Unlicensed Person to Practice Medicine

(Gobin vs. State (Okla.), 131 Pac. R. 546)

The Criminal Court of Appeals of Oklahoma affirms the judgment as to each of the defendants, O. O. Gobin and R. W. Freeman, who were charged with practicing medicine without a license, and convicted, a fine of $250 and sixty days' imprisonment being imposed on each as the punishment. The court says that much testimony was introduced on behalf of the state, but that it was necessary to consider only the testimony introduced by the defendants. Gobin admitted that he had no license to practice medicine in Oklahoma; that he was in the employ of Freeman on a salary; was practicing medicine as the assistant of Freeman; was collecting fees for his services and paying them over to Freeman. Freeman in his defense introduced a certificate from the state board of medical examiners authorizing him to practice medicine and surgery in the state. He testified also that Gobin was in his employ on a salary; that Gobin was practicing medicine under his directions and receiving fees therefor which were turned over to him.

There was no question but that Gobin's conviction was entirely proper, and the judgment as to him should be affirmed. Freeman, however, had the required certificate, and so far as his own acts were concerned independent of Gobin he could not be convicted. On the prosecution of a person charged with violating the medical practices act on the ground that he does not possess an unrevoked, valid certificate from the state board of medical examiners, the production at the trial and the introduction in evidence of such certificate is a complete defense of such charge. This rule, however, is not intended to, and does not, protect such person from prosecution if he aids and abets another to violate the medical practice act in so far as his connection with such other unauthorized person is concerned.

A person who does not possess a valid, unrevoked certificate from the state board of medical examiners is not entitled to practice medicine under the laws of Oklahoma, except in emergencies and such other cases as are specifically exempted by the statute, and this is true even though he works with or under the directions of a duly authorized practitioner; and it is immaterial whether he works for a fee, percentage, or on a salary.

The trial judge instructed the jury that if they found beyond a reasonable doubt that the defendants Freeman and Gobin entered into an agreement by the terms of which Freeman signed up prescriptions in blank to be used by Gobin in his absence, by filling in such prescriptions over the name of Freeman, and prescribing medicines for patients for a compensation, and that pursuant to such agreement between them Freeman did leave prescriptions signed in blank by him for Gobin, and did authorize Gobin to receive patients in his absence and to treat and prescribe for such patients for a compensation, from said patients to Gobin, or to Freeman, or to both Gobin and Freeman, and that Gobin did it, and further found, beyond a reasonable doubt, that Gobin did not have the certificate required by law to practice medicine and surgery, then it would be the duty of the jury to find both Freeman and Gobin guilty, although they should find from the evidence that Freeman did have a valid certificate from the proper state authorities to practice medicine and surgery.

Section 2045 of the Compiled Laws of Oklahoma, 1909, provides that "All persons concerned in the commission of a crime, whether it be a felony or a misdemeanor, or whether they directly committeed the act that constituted the offense or aided and abetted in its commission though not present, are principals." Under this statute, Freeman, if he aided and abetted Gobin in a violation of the medical practices act, would be guilty and subject to punishment, not because he (Freeman) did not have a license to practice, but because Gobin did not have, and because he (Freeman) aided and abetted Gobin in the commission of the offense. It was not contended that Freeman did not know Gobin was without authority to practice medicine in Oklahoma.

The law and instructions of the court properly applied to the facts were such that the jury would not have been warranted in finding Freeman guilty of practicing without a license. But, under the instruction of the court quoted and the facts, the jury was authorized and fully warranted in convicting Freeman of aiding and abeting Gobin in case it found from the facts that Gobin did not have a certificate or license to practice medicine in the state.

The medical practices act does not any more contemplate or authorize a registered physician going out and employing all the unauthorized quacks in the country to aid and assist him for a compensation or otherwise, except in emergencies, in the practice of medicine, than it does the employment for the same purpose of the section hands on a railroad. The law is not only intended to protect legitimate practitioners, but also to protect the public against being imposed on by an incompetent person holding himself out as a physician. The laws of this state were enacted to be observed and enforced and not to be evaded and violated. It is evident from this record that the defendant Freeman was seeking to aid Gobin in evading the law, and in doing so both of them violated it and incurred its penalties.

Circumstances Entitling Physician of One State to Compensation for Services Rendered in Another—Construction of New Jersey Statute—Authority of Wife to Employ Physician for Husband in Hospital—Basis of Compensation—Counterclaim to Mortgage

(Prentice vs. Ladinski (N. Y.), 141 N. Y. Supp. 1005)

A special term of the Supreme Court of New York, New York County, allows compensation to the defendant, a physician and surgeon of New York, for services rendered in New Jersey. The court says that the action was brought by the plaintiff, as trustee in bankruptcy of the estate of one Hayman, bankrupt, to foreclose a mortgage given by the defendant to another party, and by the latter assigned to Mr. Hayman. The defendant set up a counterclaim of $2,500 for medical services rendered to Mr. Hayman in his last illness. Mr. Hayman, harassed by business troubles, had attempted to commit suicide at a hotel in Newark, N. J., whence he was removed to the Newark City Hospital. His wife was communicated with, and she had the defendant summoned, who came to the hospital the same afternoon, which was Sunday, and was thereafter in constant attendance on the patient until Thursday evening. He then was absent from the hospital until Friday morning, and remained until Friday night, when he finally left, having given up hope. The patient died Saturday morning. When Mr. Hayman was first taken to the hospital, which was a public hospital, treating patients without pay, he was put in a public ward with other patients; but after the defendant's arrival he was transferred to a room reserved for special cases, and which he occupied alone. While the rules of the hospital did not permit the defendant formally to take charge of the case, the hospital physicians and surgeons extended to him every courtesy and all the freedom which the rules of the hospital permitted. The defendant was in constant attendance at the bedside of the patient, and his suggestions as to treatment were complied with, and some treatment he himself administered. At his suggestion an operation for transfusion of blood was performed. Another surgeon, also of New York City, was, on the recommendation of the defendant, called in to perform this operation.

The evidence, the court holds, did not warrant the inference which the plaintiff sought to draw that the defendant rendered the services in question as a friend, and not for compensation. The defendant had been Mr. Hayman's physician for years. It was also true that he had been an intimate friend of his. While this circumstance might have had the effect of rendering his professional services to his friend more assiduous and more anxious than they might otherwise have been, it manifestly did not change the character of the services. The failure of the defendant to make any charge on his books for this service and to send a bill for the same had no particular significance, because he knew that the estate was bankrupt, and, as he explained, he did not, until afterward, understand that he was entitled to make a charge for his services as a counterclaim to the mortgage.

The plaintiff also argued that, although a licensed physician of another state not licensed in New Jersey may act as a physician or surgeon in that state if he desires, without rendering himself subject to punishment, yet he may not recover fees for such service. Without quoting and going into an examination at length of the New Jersey statutes on this subject, the court thinks that those statutes were not intended to prevent the recovery of compensation for medical services rendered under such circumstances as those proven in this case.

It seems to the court that the purpose of the New Jersey statute, when read as a whole, is clear, and that it is only those who either reside or sojourn in the state of New Jersey that are subject to the requirements of the act, and that the legislature intentionally left entire freedom to physicians of other states to render professional services within the state of New Jersey in an occasional way, as distinguished from opening an office or appointing a place to meet patients, which latter, it is expressly provided, shall constitute a practitioner a sojourner in the state and subject him to the requirements of the act. It is a matter of common knowledge that great numbers of residents of New York state and Pennsylvania spend a large portion of their summers in New Jersey, and it is quite evident that the legislature of the state of New Jersey meant to leave entire freedom to such residents to call their regular family physicians, or such physicians as they might select from other states, to render them professional service. But whether or not the court is right in its construction of the New Jersey statute, it thinks that this case might, if necessary, be decided irrespective of the New Jersey statute, as the parties were all residents of New York state, the contract was made in that state, and the action was brought in that state.

Passing to the question of the authority of the wife to employ the defendant, the court does not think that in this case there could be any serious question as to such authority. She employed the same physician that her husband had been in the habit of employing for years. It was plain from the evidence that the condition of the patient was so critical that the physician was warranted in remaining in constant attendance. The wife was also at the hospital during the entire time and was aware of the continuous attendance of the physician. It was not incumbent on the wife to send the defendant away, on the theory that the hospital physicians could and would render all the service necessary. The case was a most critical one. If the patient's life was to be saved, the unremitting attention of a skilled physician was called for; and such attention could not, in the nature of things, be received from the hospital physicians, there being between three hundred and four hundred patients at the time in question.

But as to the compensation to be allowed the defendant, the court is in accord with the contention of the plaintiff that, although the evidence showed the defendant to be an operating surgeon of great skill, nevertheless for his attendance on this patient he should be compensated rather on the scale of charges for services of a family physician than the much higher scale of services of an operating surgeon. He performed no operation. The operation that was performed was performed by another surgeon of his selection; he himself being so worn out by his vigil of the night before that he was not in condition to perform it. The testimony of the numerous medical experts as to the value of the services rendered varied widely. On consideration of all that testimony and of all the facts in the case, the court fixes the compensation for such services at the sum of $750, to be deducted from the amount remaining unpaid on the mortgage.

Society Proceedings

SEVENTEENTH INTERNATIONAL MEDICAL CONGRESS

August 6-12, 1913

(From Our Regular and Special London Correspondents)

(Continued from page 701)

Section on Surgery

Sir W. Watson Cheyne presided at the first meeting (Wednesday, August 6) of the Section on Surgery in the Physics Theater of the Imperial College. He was supported on the rostrum by the Secretaries of the Section, Mr. D'Arcy Power, Mr. Raymond Johnson, Professor Thorburn, Professor Sinclair, while on the benches many of the most distinguished surgeons of the day were seen, among them Professor Lucas-Championnière and Professor Hartmann of Paris, Professor Freiherr v. Eiselsberg of Vienna, Professor Dollinger of Budapest, Sir William Macewen of Glasgow and Professor Oskar Bloch of Copenhagen.

The President's first word was one of welcome. He could not help, he said, contrasting the condition and scope of surgical science of the present day with that of a generation ago when the Congress last met in London in 1881. That date seemed to him to mark the close of the old régime and the introduction of the new. The men who had laid the foundations of the great superstructure of surgery were no longer with them. And they were still mourning the loss of Lister, the greatest genius in surgery, the man whose work and love for humanity had brought light and health and rejoicing to countless homes. Surgery had far outstripped medicine in the progress of her art. But he would not like to say what new developments might not open up to medicine, so that in another thirty years' time the relative positions might be reversed. At present they removed large portions of the body to cure disease, but that could only be justified till such time arrived when disease would be cured by other means developed along the lines of serum and vaccine therapy.

Professor Lucas-Championnière followed with a warm-hearted, eloquent tribute to the memory of Lister. Professor Freiherr v. Eiselsberg and Dr. Oskar Bloch spoke also in the same strain.

Dr. G. Le Filliâtre of Paris read the first paper on spinal analgesia. He presented statistics of 116 cases of patients in a very weakly or cachetic condition on whom he had operated with the aid of spinal analgesia in lesions of the head, neck, thorax, stomach, liver, kidneys and lower limbs. In every case the anesthesia was perfect, and in those cases which for the most part could not otherwise have received the benefit of surgery the operative mortality was only 3.5 per cent. The author concluded that operative shock was nothing more nor less than shock due to general narcosis by chloroform or ether and that shock disappeared with his method of producing analgesia and the mortality sank almost to nil in these extremely feeble patients.

This question was discussed by Professor Dollinger (Budapest) who advocated local anesthesia preceded by morphin, and who had performed cholecystectomy six times by this method, by Prof. von Eiselsberg (Vienna) whose preference was for general anesthesia in children, and by Professor Hartmann (Paris) who was totally in favor of general anesthesia, especially in abdominal work.

Surgery of Gastro-Intestinal Conditions

Mr. Herbert J. Paterson (London) in a paper on "The Physiology of Gastrojejunostomy" presented arguments in favor of regarding the benefits which follow gastro-enterostomy as due to physiologic processes and not merely to mechanical drainage, which were supported by statistics of gastric analyses. He concluded that a certain amount of bile and pancreatic juice entered the stomach after this operation, that the total acidity of the gastric contents was diminished by 30 per cent., that gastric digestion was impaired but not lost after the operation, and that the mobility was unaltered except in pyloric stenosis. He thought that occlusion of the pylorus was an unnecessary complication of gastrojejunostomy, and that excision of simple ulcers was not required, and further, in his view it was contrary to clinical experience that malignant degeneration of gastric ulcers was frequent after gastro-enterostomy.

"Pancreatitis and a New Factor in Its Causation," was the title of an original contribution by Dr. E. Archibald (Montreal). Clinically he had observed that when a gall-stone occupied the ampulla of Vater bile was dammed back and could force its way up the pancreatic duct. Before this could happen it necessarily must overcome the restraining action of the sphincter at the outlet of the duct of Wirsung. He had made some experiments to find out how much pressure was required to accomplish this and found that generally a pressure five or six times greater than the ordinary bile pressure sufficed. In a case of pancreatic cyst in the clinic of Dr. Armstrong of Montreal he had examined the fluid and found bile. The keynote, therefore, of the treatment of certain forms of pancreatitis was not drainage affecting the pancreas or its duct, but reduction of the excessive pressure in the biliary system by cholecystostomy. He suggested that a proper operation for certain cases of chronic and subacute recurrent pancreatitis would be cutting this sphincter in the ampulla.

Dr. L. Mayer (Brussels) in a short paper on the subject urged the advisability of more extended employment of transverse incisions in abdominal work.

In the absence of Dr. Russell S. Fowler (New York) his communication on the "Elevated Head and Trunk Position in the Surgical Treatment of Abdominal Lesions" was read by Dr. Polak (Brooklyn). The paper narrated the circumstances under which this now well-known therapeutic measure was discovered and detailed the anatomic and mechanical basis on which it was founded. He was still convinced that it contributed largely to the lowering of the death-rate, but he had no new facts or theories to offer.

Nor was there much that was new in the contribution of Dr. Waters F. Burrows (New York) on "Postoperative Intestinal Stasis" and the intra-abdominal use of oil. This measure has been known to surgeons for over two years and was suggested by Dr. D. P. D. Wilkie at the meeting of the British Medical Association in 1911 as a means of preventing the formation of adhesions in acute septic peritonitis. Dr. Burrows held that apart from the gross complications which might occur after an abdominal operation there were sometimes symptoms of obstruction which he thought were associated with regional or segmental gut spasm. This spasm occurred mostly in the small intestine and probably it could be referred to more or less minute traumatism arising in the manipulations of the operation. The evil effects of these abrasions could be combated by pouring about 6 or 8 ounces of "oleum petrolatum" into the abdominal cavity so that a coating of oil would prevent adhesions and promote the normal peristaltic movements. He had carried out a series of experiments to show the harmlessness and value of neutral mineral oil so used.

Professor Krynski (Warsaw) presented notes of a case which induced him to argue for the recognition of cirrhosis of the mesentery as a clinical entity. The patient had suffered for twenty-two years with abdominal pain, irregular attacks of constipation and diarrhea, great increase in size of the abdomen, and palpable tumor. Ileocolostomy resulted in great improvement. The condition was a chronic inflammatory process; a fibrosis characterized by superabundant development of connective tissue and loss of fatty and elastic tissues.

The second meeting of the section (Thursday, August 7) was devoted to "Discussion of the Operative Treatment of Malignant Disease of the Large Intestine, Exclusive of the Rectum," the essayists being Professor Rafaele Bastianelli of Rome and Professor Körte of Berlin. Professor Körte's paper was an elaborate study of the subject, replete with historical references and statistics drawn from all sources. The particular dangers of resection of the large intestine for malignant tumors, collapse and peritonitis, depended chiefly on the anatomic relationships of the resected portion of the bowel as well as on the difficulty of preventing soiling of the peritoneum. In acute intestinal obstruction it was possible only to adopt a simple procedure for emptying the bowel, namely, colostomy, with the intention of going on to perform a secondary radical operation in two or three stages.

In chronic slowing of the intestinal flow the two or three-stage operation by suture (colostomy, resection of the tumor, closure of the colostomy) was the most certain operation, though the slower method. Where it was possible to thoroughly empty the bowel, insure perfect hemostasis and absence of tension of the sutured bowel-ends, the one-stage resection and suture was best. The various anatomic relations of different portions of the great intestine demanded various operative procedures. The expectation of long-standing healing was relatively favorable in carcinoma of the great intestine. As regards palliative operations, entero-anastomosis in the absence of obstruction was the best operation. Colostomy, and that may mean cecostomy, was the method of choice where obstruction existed. Colectomy or entero-anastomosis was to be performed secondarily to emptying of the bowel.

Professor Bastianelli (who spoke in English) said that surgeons should adhere to the principle of not interfering with the primary tumor if obstruction existed. Only in some cases of tumor of the cecum was it possible to risk violating that principle, and mainly because an artificial anus in the cecal region was highly objectionable. But in the case of a left-sided tumor, formation of the cecal anus was the operation of choice. He had never seen exhaustion result from the existence of an artificial anus. The ideal operation was primary excision of the tumor in one stage; it certainly was the operation of choice in right-sided tumors, and was applicable in all except tumors situated low on the left side where primary suture was practically impossible. The removal must be thorough and must include not merely a large portion of adjacent bowel, but the lymphatic apparatus as well. The death-rate in right-sided tumors was 9 per cent., and the left side 15 per cent. Modern technic could not bring about great improvement in the results of palliative operations; these results really had nothing to do with the operation itself, but depended on the patients's condition. As to radical operation, the principle must be strictly adhered to not to attempt it in the presence of complications. The comparatively slow growth of the neoplasm with its late lymphatic and visceral dissemination and the possibility of earlier diagnosis were important factors to consider.

Dr. A. L. Soresi (New York) demonstrated a method of end-to-end suture of the bowel which simplified the operation and permitted it to be accomplished by means of only one row of sutures. But as it appeared to require the employment of a piece of rubber tubing which was left in the lumen it was not regarded by some members of the section as an advance.

Statistics were contributed by Sir Frederic Eve (London). He was of the opinion that unless the local and general conditions for primary resection were distinctly favorable the average operator—in the London Hospital sixteen surgeons in all werre responsible for the work—would best consult the safety of the patient by doing the three-stage operation. The mortality had not increased since the extensive modern radical operations came into vogue; the mortality of resection with small margin of healthy bowel was 52.5 per cent., whereas the extensive operations of the Jamieson and Robson type had a mortality of only 29 per cent.

Mr. Charters Symonds suggested that resection should be performed even in the presence of metastasis in the liver provided it were not extensive and instanced a case in point in which a patient lived for nearly two years after resection even though there was a small metastatic deposit visible in the liver. Similarly in the anemia found in such cases he thought it might be sometimes advisable to remove the original tumor and he had known the anemia to disappear completely after so doing.

Appendicostomy in preference to cecostomy in irremovable cancers was urged by Mr. W. G. Spencer (London). He held that if a large catheter (14 English) were introduced through the appendix into the cecum in such a way that fluid could be run in and fecal fluid siphoned off, it was a sufficient and a more suitable mode of treatment than the artificial anus. He did not believe that the regular passage of feces irritated a cancer of the colon.

Short contributions to the debate were made also by Mr. H. J. Paterson (London), Prof. A. E. Barker (London), Professor Krynski (Warsaw), Dr. Keppich (Budapest), Dr. J. B. Murphy (Chicago), Professor Hartmann (Paris) and the essayists replied.

Professor Bastianelli held that the one-stage operation was the ideal one; there was a technical as well as a clinical ideal to be sought. Very extensive operations were sometimes easier to do than limited ones as then the bowel could be brought outside the wound in the abdominal wall. Whether the pathologists were right or not, in regarding distant permeation as the rule, he favored operations of wide scope. He associated himself with Professor Körte in hoping for earlier diagnosis, but meanwhile early diagnosis was difficult and problematic.

At the afternoon session of August 7 Dr. Angelo Chiasserini (Rome) read a paper on "Experimental Inflammatory Lesions of the Hypophysis and of the Hypophyseal Region." The experiments were performed on dogs and were carried out by inoculating that region with tuberculous material and with sporotrichosis. The result of his investigations was to show that quite definite inflammatory changes took place.

Dr. F. H. Albee (New York) gave an account of 175 cases of transplantation of bone, the grafts being taken from the tibia. Of these cases 145 were cases of spinal curvature. His work is well known in the United States.

Dr. J. B. Murphy (Chicago) then gave a lantern demonstration of the clinical results attained in "Arthroplasty and Osteoplasty." His work is familiar to the profession in the United States.

Dr. H. Eckstein (Berlin) gave a lantern demonstration of the results he had been achieving in the rectification of nasal defects. The ordinary type of saddle-nose could be readily treated by injection of hard paraffin and he was also able in many cases to make good the loss of the tip of the nose by similar injection. Dr. Stein (Wiesbaden) criticized the employment of hard paraffin and held that soft paraffin was less likely to give rise to embolism and thrombosis.

The last paper for the day was read by the secretary on behalf of Prof. R. Minervini (Naples). He advocated the employment, where possible, of whole skin grafts taken from newly-born babies who had died within a few hours after birth. He was able in five cases to make excellent use of large grafts obtained in this way.

Discussion on Renal and Vesical Tuberculosis

The fourth session (Friday, August 8) of the Surgical Section consisted of a joint meeting with the Section of Urology to discuss "The Diagnosis and Treatment of Early Renal and Vesical Tuberculosis." Professor Rochet of Lyons and Dr. Hans Wildbolz of Berne were the essayists.

Professor Rochet deprecated any attempt to formulate definite and precise rules in a question so delicate and so diversely regarded by acknowledged authorities. In regard to unilateral kidney tuberculosis a "granular" lesion discrete and not deeply placed seemed inevitably to go on to an ulcerating and caseating stage with fatal termination, but there was no proof that this early condition did not, as in other organs, heal. The diagnosis of this early granuloma, not yet ulcerocaseous, was obscure and difficult. In a patient suspected to suffer from early tuberculous disease and in whom the urine from one kidney contained bacilli with positive inoculation of guinea-pig he would not advise immediate operation, but would wait for three new conditions to develop: (1) a slight degree of pyuria, (2) a certain diminution of the functional value of the diseased kidney, and (3) such complications as serious repeated hemorrhages, pyrexia, anemia and bladder symptoms. Whenever symptoms pointed to formation of ulcer or caseation, operation was called for. As to specific treatment by tuberculins, antituberculosis serums and immunizing substances, he had to admit that his experience was limited, though he did not think they could do all that was claimed for them. The treatment by the immune bodies of Spengler he did employ in the expectant period, and he thought with some success. These bodies are obtained by extraction from red blood-cells of rabbits immunized to tuberculosis.

In bilateral kidney tuberculosis the lesions were probably not equal on both sides. In these conditions specific treatment was indicated.

Early tuberculous infection of the bladder in so far as it was almost inevitably due to secondary infection from the kidney (90 to 95 per cent.) was cured when the kidney was treated. In treatment of bladder disease persisting after nephrectomy, or in the few cases of primary infection or after infection from the genital organs, he advocated washing the bladder with creosote solution and administration of pills composed of iodoform, arsenate of soda and creosote. Specific treatment could be used only in cases in which vesical infection was associated with advanced renal and genital disease.

Dr. Hans Wildbolz observed that early tuberculosis did not refer simply to the patient's first symptoms, as he had known cases to be tolerably advanced before the patient sought advice. He had found a kidney three parts cavernous in a patient who for only ten days had complained of urinary symptoms. In over 300 cases of tuberculous kidney examined by him only twenty-five were in the early stage; in all the others the disease was advanced. He indicated some symptoms which drove the patient in the early stages to his physician—disturbance of general health, lessened vigor and ability for work; local signs referred in more than two-thirds of the cases to the bladder (Rafin) (43 per cent. of his own cases complained of cystitis); kidney pain of dull or occasionally neuralgic character; frequency of micturition, sometimes incontinence; pain in the bladder even before that organ became infected; hematuria, a common early sign (out of 300 cases he found it only twice as the first symptom), was sometimes very severe. Then the urologist was able for himself to observe persistent slight albuminuria, polyuria, alternations in blood-pressure (it was necessary to exclude chronic nephritis in which polyuria and albuminuria were also found), acidity of the urine, pyuria, cystoscopic examination (often negative, though he had observed redness and infiltration of mucous membrane not specifically tuberculous). In 70 to 80 per cent. of all cases tubercle bacilli were found in centrifugalized urine, but inoculation experiment was the surest test. It had to be kept in mind that tuberculous bacilluria had been found in cases of phthisis in which neither kidney, bladder nor genital organs were infected.

The diagnosis of tuberculous disease of the kidney with present-day methods could be made with certainty only when pus cells and bacilli were found in the urine of that kidney whose function was unmistakably though slightly disturbed.

Tuberculin treatment in the early stage had had more claims put forward on its behalf than any other. But it seemed to him that for only very few recorded cases could the claim of permanent cure be sustained. He gave his own experience of thirteen carefully observed cases in which treatment had been conducted for from one to four years, and his conclusion was that not a single one of them could be said to be cured, and eight later required nephrectomy. The results of early nephrectomy seemed good on the whole, but the cases were too few to found conclusions on. He believed, however, that as soon as unilateral tuberculous disease of kidney was with certainty diagnosed, that kidney should be removed.

Dr. A. Fullerton (Belfast) pointed out that the disease might progress rapidly so as in a few weeks to render the patient's life intolerable or it might go on for ten years with but little disturbance. Hope of spontaneous cure was not to be relied on. He had had only three cases of primary disease of the bladder. The absence of pus and albumin were not absolute proof of the integrity of the kidney. Tubercle bacilli were found in 80 per cent.; frequent examinations for the bacillus were necessary. The cystoscope and ureteral catheter were the most important instruments of diagnosis. Removal of the affected kidney was the only absolute cure.

Professor Kümmel (Hamburg) had had 60 per cent. cures after nephrectomy. Tuberculin was on the whole a dangerous form of treatment because it raised false hopes on account of the undoubted improvement following its use in the first weeks or months.

Dr. Van Houten (The Hague) treated bladder infection (which was always secondary to kidney disease) with silver nitrate solution, ½ to 2 per cent., injected once weekly.

Mr. Leedham-Green (Birmingham) was of opinion that the only cure was removal of the diseased organ. But he was doubtful if early tuberculous infection did not sometimes heal spontaneously, as it did in other parts. So long as the function of the kidney was unimpaired he would not remove it. Clinically it was difficult to estimate the stage of the disease. In children their attitude should be one of extreme caution because in them he had found tuberculous bacilluria with few pus cells or none and good functionating kidneys.

Dr. David Newman (Glasgow) demonstrated by the projectoscope the cystoscopic appearances in early renal and vesical tuberculosis. He pointed out that the most characteristic feature of the symptoms (polyuria, slight pyuria and albuminuria, occasional hematuria) was their tendency to remission, and in that lay a serious danger in so far as both patient and doctor were deceived. The premonitory symptoms of tuberculosis could appear long before the development of a gross renal lesion. In this stage cystoscopy frequently applied, and harmless as it was, was most successfully employed. When a kidney was tuberculous the orifice of the corresponding ureter indicated the nature of the lesion by changes in the color and contour of the lips of the orifice, by the size, frequency and regularity of the "shoots" of urine and by the character of the urine which escaped. His conclusions in primary renal tuberculosis were: 1. When the ureteral orifice was normal no serious disease existed in corresponding kidney. 2. When the kidney was normal the orifice of the ureter also was normal. 3. Evidence of tuberculosis at orifice was associated with tuberculosis of corresponding kidney. 4. In tuberculosis of bladder the ureter did not become involved if corresponding kidney were free from disease.

Professor Rovsing (Copenhagen) was doubtful of the possibilities of early diagnosis, and thought that these very early cases rarely came to the surgeon. After removal of the tuberculous kidney, the tuberculous bladder quickly recovered; to assist it he injects 6 per cent. carbolic acid. The efficacy of tuberculin seemed to him so problematical that its use should be limited to inoperable cases.

Mr. Hurry Fenwick (London) held that early cases of kidney mischief were diagnosable by the cystoscope. Even only three weeks after onset of symptoms he had found thickened ureter and intravesical signs. He had used tuberculin constantly for fifteen years in small doses and found that the patient's general condition improved nearly always. He believed it acted as a tonic. Our knowledge of this disease was to come from study of its progress in the female patient. Nephrectomy was a perfectly safe operation if performed with rigorous asepsis; the mortality need not be over 3 per cent.

Surgery of the Arteries

The chief subject for discussion Saturday, August 9, was "The Surgery of the Arterial System." Prof. Rudolph Matas, New Orleans, made a rapid survey of the whole range of the new movement in surgery, described the suture of both arteries and veins, arteriovenous anastomosis of various kinds, transplantation of arteries and veins and brought forward laboratory as well as clinical evidence to show the feasibility of these various procedures. In regard to vascular implantation of arteries and veins autogenetic methods were more suitable than heterogenetic though these were not wanting in success. The segment of an artery or vein could be grafted to another, or branches of a parent trunk could be reimplanted on the same vessel at different levels. Arteries and veins could be patched with portions of blood-vessels or other material. The main portion of his paper was devoted to the method of treating aneurysm by suture associated with his name—intrasaccular suture or endo-aneurysmorrhaphy. The latest statistics included an analysis of 215 reported cases. The results fully justified the confidence placed in this operation.

Dr. C. A. Ballance recognized that surgery of blood-vessels had advanced greatly. He specially spoke of the obliterative and reconstructive treatment of aneurysms recommended by Matas and thought that since Hunter no advance had been made till Matas began his work. In his own view, except in the treatment of aneurysm of the aorta and some other great vessels, and in special circumstances, Matas' method was not likely to find general acceptance. He regarded popliteal aneurysm as the type best suited for Matas' operation. But nevertheless the practical advantages and the extreme simplicity of the Hunterian operation seemed to him still to prevail. He thought the Hunterian operation for popliteal aneurysm was the greatest advance in surgery ever made by the single act of one man. Matas' operation should be reserved for those cases in which the older operation is inapplicable.

Dr. A. L. Soresi of New York showed his apparatus for suture of blood-vessels. He had had made a small clamp which held the ends of the vessels to be joined in such a way that minute hooks held back a cuff so as to expose the intima all around. Then intima was sutured to intima by the insertion of very small gold wire clamps after the fashion of Michael's clamps. A single row of these was enough to effect a complete and safe junction.

Dr. Davis (Brussels) said that Professor Oppel of St. Petersburg had said that ligation of both artery and corresponding vein gave a better final circulation than ligature of the artery alone. The principle was sound but on one condition only, that the vein should be tied *after* the occlusion of the artery. He had proved the efficacy of the method and the truth of the principle by some experiments.

Dr. Ernest Jeger (Berlin) gave a short account of some of his studies. Eck's fistula or anastomosis between portal vein and inferior vena cava he had performed repeatedly on dogs. Magnesium tubes were a useful support to blood-vessels in suturing, as the magnesium afterward became absorbed. He demonstrated specimens of transplanted kidneys from their normal situation to the neck, the carotid artery being joined to the renal artery and the jugular vein to the renal vein. He had even inserted one end of a piece of vein into the left ventricle of the heart and the other into the aorta, so that the aortic valve was put out of use. Most of these experiments were performed on animals, but he was hopeful that in time they will become applicable to the human subject.

The experience of Dr. V. Soubbotitch with traumatic aneurysms in the Balkan War was interesting. The majority of the cases had to be treated by the older methods, but in some cases he and his colleagues were able to suture arteries and veins with moderately good results.

Dr. Chiasserini (Rome) had performed thirteen experiments in transplanting flaps of fascia lata in repairing the aorta or other large vessels with such success that he recommended that tissue as very suitable for the purpose.

Discussion on Brain Tumors

The largest and most representative meeting of the Section was that which met Monday, August 11, for the discussion on "The Diagnosis and Treatment of Tumors of the Brain." The essayists were Professor von Bruns, Professor Freiherr von Eiselsberg and Dr. H. H. Tooth.

Professor von Bruns showed that operative procedures for cerebral tumors fell into two groups: (a) radical operations with extirpation of the tumor, (b) palliative operations for the relief of pressure, and these could be either primary and devised for that purpose alone, or they were performed as a scondary resort when the radical operation for some reason could not be performed.

The indications for the radical operations and the prognosis of those operations depended on three things: (a) the nature of the tumor; (b) the possibility of certain general and local diagnosis; (c) the accessibility of the tumor. Inaccessible were tumors of the third ventricle and many in the substance of the hemisphere. All others were accessible, but with very different degrees of danger.

Professor von Eiselsberg spoke of the great difficulties in operating on tumors of the hypophysis. He had tried to attack these tumors by the nasal route, but thought the risk of operating through a passage not absolutely aseptic was great. He showed several specimens and pictures of cases operated on. He strongly advocated early operation and held that it was inhuman not to operate on brain tumors.

Dr. Howard H. Tooth's report concerned itself with the question of results of surgical treatment. A high mortality was inevitable at the best. They were not to be dismayed by it nor relax efforts to relieve patients. In frontal tumors where removal of tumor partial or complete was done he found that in glioma the average postoperative survival period was ten months; in endotheliomas which pressed on but did not infiltrate the brain and which could be removed without great difficulty the mortality was 46.6 per cent. In tumors of the central region comprising 65 cases of glioma, sarcoma and carcinoma, the average postoperative survival period was ten months. The percentage of recoveries in endotheliomas was 66.6. There were only a few cerebellar cases, with four recoveries. Two tuberculoma patients died within two months though the growth was completely removed. Decompression by craniectomy in one or two stages was followed by an appreciable lowering of pressure. From his tables he could draw no conclusion for or against the method.

Prof. Harvey Cushing said that the relief obtained after decompression in a relatively silent area might be great. Many tumors were slow in growth and might reach a large size before disturbance took place. If a very strict interpretation of the recovery was taken, none would see more than 5 per cent. recoveries. But if the patient obtained after the operation freedom from discomforts, preservation of vision, prolongation of life, then the percentage of recoveries rose to 50 or 60. There could be no doubt that 10 per cent. would succumb after operation, even after such a simple proceeding as decompression. In the last 100 consecutive cases he found that seven deaths could be attributed to the operation. In 350 tumor cases need for operation was certified in 200; 40 per cent. were gliomas, 30 per cent. arose from glandular structures. In true endotheliomas there was none of the cellular fibrillae seen in gliomas; they were potato-like tumors which had point of origin from the dura. Two cases of enormous tumors had no pressure symptoms and no ocular fundi changes. He had had twenty-four operations for tumors in the lateral recess of the cerebellum. To reach that area he strongly advocated the large crossbow incision with, if necessary, removal of posterior half of foramen magnum. This permits exposure of the medulla, and if respiratory difficulties arose he had removed the posterior portion of the atlas while artificial respiration was being carried on with restoration of respiration.

He thought they must operate slowly in these cases with complete hemostasis. His operations sometimes lasted four hours and they often had to be done in three or four stages. Extremely delicate manipulation was necessary with the greatest possible respect for brain tissue.

Sir Victor Horsley thought accurate histologic diagnosis of tumors was most important. Earlier diagnosis meant earlier operation. He blamed the writers of text-books for their too rigid insistence on recognition of the three great classical signs, headache, vomiting and optic neuritis. These appeared late. They were end-results and the patient ought never to have reached the stage when these appeared; often by that time the tumor was irremovable and decompression only was feasible. Optic neuritis was a most valuable sign. He agreed with von Bruns in recognizing the difference between a radical and a palliative operation and held that operation might be done for differential diagnosis. In palliative operations he deprecated opening the dura, as a rule.

Professor Krause (Berlin) had operated by local anesthesia. He showed pictures of angioma of the brain, and endothelioma growing from the dura. Professor Claude (Paris) was strongly in favor of decompression to relieve symptoms. Sir William MacEwen said that the principal factors in his experience were the necessity for early diagnosis and localization. Wherever physiologists made certain of special points which bore on localization surgeons were able to go in at the part and remove the tumor. Early diagnosis and early operation went together. The classical symptoms were stated too positively, for sometimes a tumor was present even in the absence of classical symptoms. He had found a large tumor and removed it successfully where the only signs were slight paresis of the right arm and contraction of left pupil. In the motor area localization was definite and complete, but in other regions it was not so. Word-blindness, mind-blindness and word-deafness were symptoms which ought to be localizing symptoms and he had successfully operated where these symptoms were present. He had no great belief in statistics.

Professor L. M. Poussepp (St. Petersburg) had operated on thirty-one patients with brain tumor; sixteen cerebellar and fifteen cerebral. His general opinion was that success was not so much a matter of surgical technic as of precision in diagnosis, which could only be obtained by continued study of surgical neuropathology.

Dr. Byrom Bramwell (Edinburgh) thought that there were very few cases of intracranial tumor which could be completely and successfully removed by the surgeon. The whole matter turned on what they meant by recovery. If the tumor were removed and the patient left hemiplegic or blind he had not recovered at all. His pathologic experience convinced him years ago that the surgeon could do little or nothing and he had not seen reason to change from that opinion. He was, however, greatly impressed by the value of the right-sided decompression operation.

Discussion on Intrathoracic Surgery

Tuesday, August 12, Professor Sauerbruch reported on the "Present State of Intrathoracic Surgery." The factors which had been of most importance in the development of surgery of the chest, were, in the main, three: The improvement of diagnosis by means of Roentgen rays; by this method changes in the lung substance, the formation of cavities, the presence of tumor, and the stages of tuberculous disease could be demonstrated, and the alterations and improvements following treatment could be traced. He placed next the experimental researches on pneumothorax. The last factor was the introduction of methods to determine the difference of pressure within the lung in relation to atmospheric pressure.

His own experience was that operations on lungs were best performed by the aid of special apparatus to establish a negative pressure, that is, that the operator and the whole of the patient, except his head, were in a chamber whose pressure was less than the atmospheric pressure, so that collapse of lung did not occur when the pleural cavity was opened. The same object was attained in the reverse manner by making the patient breathe in a small chamber whose internal pressure was higher than atmospheric pressure; this was known as positive pressure. By these methods exploratory opening of the chest cavity was as simple an operation as exploratory opening of the abdominal cavity, and tumors could be removed.

Bronchiectasis was treated by opening into the lung cavity, and drainage. He had cut the phrenic nerve, and performed artificial pneumothorax for the purpose of putting the affected lung at rest. In tuberculous disease of lung he had performed Freund's operation of cutting the costal cartilages of some ribs to permit immobilization of the lung, and had also endeavored to bring about the same object by artificial pneumothorax, thereby causing collapse of the lung. He gave statistics of his work.

In Zurich hospitals in 1910-1913 he had operated on eighty-three cases of lung disease.

Professor Tuffier's report was read in his absence by Dr. Caillard. The ground was similar to that by Professor Sauerbruch.

Sir William MacEwen demonstrated a patient operated on by him eighteen years ago, whose left lung had been removed in its entirety for tuberculous disease. The patient was a strong, healthy-looking man whose left side was hollow and fallen in. He was engaged steadily at work. At the time of the operation the right lung was diseased, but the removal of the hopelessly diseased lung was followed by improvement in the condition of the remaining lung. That experience had been found in four similar cases. In all these cases the apex of the diseased lung had been adherent to the great vein at the root of the neck, and at a later stage in the last four cases the vein and that piece of lung were removed.

Sir William MacEwen's second point was with regard to the differential pressure theories and apparatus of Sauerbruch and others. His belief was opposed to theirs that all these elaborate apparatus were necessary. It was not atmospheric pressure which held together the two surfaces of the pleura, the lung surface and the inner lining of the chest wall. He attempted to demonstrate this by suitable apparatus. He had consulted the late Lord Kelvin, and he had recognized that it was a much greater force, which he suggested should be called "molecular cohesion." Professor MacEwen proved to the Section by an experiment on the table that atmospheric pressure did not hold together two pieces of glass of uniform smooth surface. He believed that the pleural surfaces were held together by molecular cohesion, and that so long as the opening in the pleural cavity was patent to the atmosphere the collapse of the whole lung will not take place. In regard to cancer of the lung, he had given patients great relief by opening into the lung cavity, clearing out the pus and broken-down lung substance and allowing the cavity to close by granulations. He had not cured the cancer, but the patient's death was easier.

Mr. Morriston Davies (London) had performed artificial pneumothorax for phthisis by collapsing the lung and also immobilization of the ribs for the purpose of keeping the lung at rest in phthisis. He advocated strongly frequent and repeated radioscopic examination.

Dr. Meltzer and Dr. Charles Elsberg of New York, Mr. G. E. Gask of London and Dr. Davis of Brussels all demonstrated methods of anesthesia to be employed in operations on the lungs. All except the last were for purposes of intratracheal insufflation. Dr. Meltzer was the pioneer in this form of anesthesia.

Section on Diseases of Children

The President, Dr. Eustace Smith, opened the work of the section Thursday, August 7, by a short address. After extending a welcome to the visitors he referred to the very special character of diseases as they occurred in children, and traced the growth of pediatrics as a special subject. He concluded by expressing a hope that the new methods which had been introduced would not lead to a neglect of those older methods which had already proved useful.

The special discussion of the day was introduced by Dr. V. Ménard of Berck-sur-Mer and dealt with the "Treatment of Tuberculosis in Childhood from the Surgical Point of View," with special reference to bones, joints and lymph-nodes. He thought from the standpoint of local treatment tuberculous osteitis should be separated from tuberculous disease affecting the bones and joints. The local treatment indicated in arthritis was the conservative method, which was almost always efficient if persevered in. Surgical interference was required in suppuration; as the result of associated accidental infections when the disease affected particular joints. Such an operation was drainage or a form of resection which was really drainage on a large scale. The fatality of operative procedure was very small except in the case of hip-joint disease, but here it formed no contra-indication, for it was necessary to save life. The results of operation were good if the after-care was rational and persevering. In spite of the improvement of medical treatment in disease of the lymph-nodes there still remained a part for surgery to play in this condition to free the patient quickly from large masses of lymph-nodes. Whether operated on or not the patient could only recover if placed under favorable conditions for a long time.

Mr. Harold J. Stiles (Edinburgh) continuing the discussion spoke especially of prophylactic treatment and referred to recent work in Edinburgh in this direction. He thought that Koch and his disciples committed a serious error when they minimized the importance of milk as a source of infection in children. Mr. John Fraser had undertaken a research as regards bone and joint cases in the laboratory of the Royal College of Physicians of Edinburgh. His results were of extreme significance. Of the seventy cases investigated, thirty were cases of joint disease and thirty-one of bone disease. Of the seventy cases the bovine bacillus was present in forty-one, the human bacillus in twenty-six and both types in three. All the patients but three were under 12 years of age. It was interesting that in each of the three adults the bacillus was of the human type. Forty-one of the children were under 4 years of age, and in these, in no less than 78 per cent., the disease was due to the bovine bacillus. This bacillus was the organism found in all the children less than 12 months old, and each of these had been entirely nourished on cows' milk. In none of the children artificially fed had the milk been sterilized. Dr. A. P. Mitchell had worked on the etiology of tuberculous diseases of the cervical lymph-nodes. He had investigated seventy-two consecutive cases of lymph-nodes operated on at the Royal Edinburgh Hospital for Sick Children. In nearly all the cases the disease involved the upper carotid set of deep cervical lymph-nodes. Of the seventy-two cases it was found that sixty-five, or 90 per cent., contained the bovine bacillus, and only seven, or 10 per cent., the human form. Thirty-eight occurred in children under 5 years of age. Of these all but three were bovine. Out of sixty-five children infected with the bovine bacillus there was not a single case in which a history of pulmonary tuberculosis could be obtained in the family. There were only three instances in which a history of pulmonary tuberculosis could be obtained in the parents, and in each of these three it was the human form of bacillus which was isolated from the cervical lymph-nodes. Dr. Mitchell's investigations revealed a much larger percentage (practically a third of the cases) of primary tuberculosis of the tonsil than had hitherto been recorded. It was to be hoped that as the result of these investigations the medical profession would realize its responsibility and by educating public opinion bring pressure to bear on the government and the public health authorities to take effective measures to stamp out bovine tuberculosis among dairy cows. He (Dr. Stiles) thought that tuberculosis of the lungs in adults was usually the result of infection through the respiratory tract, while in children tuberculous infection was usually through the alimentary tract. It was very important that the milk should be sterilized which was used for the artificial feeding of infants unless it could be guaranteed free from tubercle bacilli, and that sterilization should be employed also in all households where the children drink milk.

Among those who took part in the discussion which followed were Prof. von Pirquet, Professor Tedeschi, Dr. Andrieux, Dr. Comby, Dr. d'Oelsnitz, Dr. Treplin, Dr. Binney, Dr. Koplik and Dr. Nordheim.

In the afternoon Dr. David B. Lees (London) dealt with the diagnosis of early pulmonary tuberculosis in children. He emphasized the virtue of careful methods of percussion, pointing out that such examination was all the more important in children, since as a rule, no sputum was obtainable.

Dr. P. von Pee of Verviers spoke of the value of "orthopercussion" as described by Goldscheider and by Curschmann and Schlager. It was based on the following principles: (1) the percussion should be as gentle as possible so that the sound could only just be heard; (2) as small an area as possible should be percussed, by application to the chest, not of the terminal phalanx, but by the end of the finger placed vertically in the position of Plesch; (3) percussion should be made with the pleximeter finger parallel with the midline of the body. He examined symmetrically the following regions: (a) the area between the two sites or insertion of the sternomastoid muscle; (b) the subclavicular triangle; (c) the area outside the subclavicular region; (d) the area of the manubrium sterni and the sternoclavicular articulation. The diagnosis of pulmonary tuberculosis in the newly-born was always difficult, and as it had been shown that the tuberculin tests gave a positive result more frequently as age advanced, the difficulty became worse. Seeing the frequency of a positive reaction to the bacterial test it was important to give to ordinary clinical methods the credit which was their due.

Dr. d'Oelsnitz (Nice) spoke of the diagnosis of disease of the thorax by means of radiography. In the discussion which followed these papers Dr. Lapage supported Dr. Lee's contention as to the value of Roentgen rays in the early diagnosis of tuberculosis in children. He thought that the earliest signs were to be found at the roots and not at the apices.

Dr. Findlay (Glasgow) read a paper on the portal of entry of tubercle bacilli. He had by means of special technic been able to inject bacilli into the stomach without insufflating the lungs. The difficulty in avoiding this latter had rendered much former work valueless. The results of his experiments went to show that infection did not occur through the intestine in the absence of a local lesion.

Dr. Coit, Newark (U. S. A.) in a paper dealing with the viability of children deprived of women's milk during the first year of life, spoke of the need of some method of estimating the value of sufficient means of saving infant life at this period. Collaboration between scientific workers and social or philanthropic workers was necessary. He exhibited "score cards" which he had found useful as indicators of the value of philanthropic and other measures.

Discussion on the Ductless Glands

Saturday, August 9, Mr. Hastings Gilford (Reading) read a paper on "The Influence of the Ductless Glands on Development." He said that to one who attempted to assimilate the information on the ductless glands which had been collected by Sajous, Swale Vincent, Biedl or by Cushing, or who went to the sources of their supply, could not but be struck by the growing importance of the subject. At the same time it became evident that this information could not, as yet, be brought to a focus. Information as to the uses of the ductless glands must still be gathered mainly from clinical, surgical and post-mortem study. The subject was one of correlation, not so much of correlation itself as of the excitement or depression of correlation. In all probability it was the mere mechanical penetration of the germ cell by the sperm cell which was the stimulus for the first correlation in all vertebrates, the fusion of sperm with germ afterward supplying that blend of characters which constituted complete fertilization. Next there came a period of development in which as yet there were no ductless glands, when, as in plants, the necessary stimulus to correlation was both simple and direct. For a time there must exist in the primitive embryo some simple secretive mechanism which later on would be gradually segregated into organs and become ductless glands, devoted to the production of hormones to excite and harmonize the action of widely separated organs. It might be suggested that this primitive faculty of cells was never lost and that in after life the ductless glands did not monopolize the power of chemical stimuli to correlation, but that all tissues possessed some degree of the same property. It might be in some such way as this that local correlations could be explained. Thus, when a segment of a long bone was destroyed in infancy the growth of muscle, fat, vessels, nerves and skin did not continue as on the sound limb. On the contrary, a considerable degree of adjustment took place. Such correlation was not solely the outcome of disuse, for a similar process was at work in the limbs of the rickety and the achondroplastic. Local adjustments of this sort varied greatly in their completeness. It was true that achondroplasia was one of the disorders which had been attributed to deficiencies of pituitary secretion, but on the other hand, the locality and nature of the changes seemed to point to the skeleton as the prime seat of the disease. Another disorder which appeared to point to correlating influences apart from ductless glands was nucrocephaly. He said that the object which he had before him was to emphasize the doctrine just brought forward by Bernard, that although the ductless glands served an important purpose in the correlations of the body, they were only a part of the machinery of adjustment. For rapid adjustments, the nervous system came into play, and for slower adjustments one had to consider not only the ductless glands, but also that primitive capacity for adjustment which was inherent in the tissues of all parts of the body.

Speaking of the disorders of the ductless glands he said that out of the fog which at present obscured the subject a few clinical types of disease, the outcome of pathologic changes in the ductless glands, were gradually emerging. They were as yet very ill defined owing partly to overlapping of their symptoms, partly to the variability of the effects produced by similar lesions and possibly partly to the influence of such other factors as he had just referred to. Yet there was some hope that we were on the right track for the solution of the problem. It was right that we should coordinate our knowledge and formulate our theories, even though we were conscious that book knowledge and theories were fallacious.

He then considered abnormalities of the function of the thyroid gland, pointing out that though myxedema was regarded as hypothyroidism and Graves' disease as hyperthyroidism, the one was by no means an antithesis of the other. Speaking of the lymphatic system, he said that when lymphatic structures were overgrown the condition known as lymphatism was present. An infant in such a state, in its most characteristic form, was fat, pale and stolid, though the intake of food might be under the average. Lymphatic tissue apparently inhibited to some degree the action of the thyroid, the pars anterior of the pituitary gland and the sex organs. Destruction of the large tracts of the lymph system, as in Hodgkin's disease, gave rise to a syndrome in which emaciation and debility were conspicuous.

Speaking of the sexual system, he stated that all attempts to influence growth and development by extracts from the sex glands had failed. We were not in a position to conclude that the series of changes which took place at puberty were solely the result of the pouring out of secretion from the sex glands, nor were we justified in assuming that the changes at the menopause were solely due to its withdrawal. He afterward dealt with the pituitary system, stating that among the disorders attributed to defective action of the hypophysis were ateliosis and progeria.

He also considered the sexual group of diseases and those of the suprarenal system. He concluded by saying that for the answer to the question as to the causes of the defective or the excessive action of any ductless gland, one must go to genetics. This branch of biology showed that as there was a normal size and a normal action, so also was it as inevitable as light to darkness that size and function must occasionally become abnormal and fall into extremes. By studying these extremes, one arrived at some sort of conclusion, however hazy, as to the normal action of the ductless glands. In the harmony which is provided by the concerted action of the ductless glands there was reason to suppose that the leading part was played by the thyroid. This supplied a stimulus for the metabolism of the body as a whole. During infancy and childhood the influence of the thyroid was checked by the thymus gland, by the lymphatic system and perhaps by the pineal gland. These also brought about that delay of sexual activity which was so essential to the proper maturation and stability of the somatic faculties. Probably the first to break through this cordon of conservative influences were the adrenal glands, which awakened the dormant sexual organs and hastened the growth of the muscular and skeletal systems. At about the same time the skeletal system was still further stimulated by secretions from the pituitary gland. This secretion hastened the development of every organ in the body, including the sex organs. These latter now ripened apace, and assisted by the combined action of the ductless glands, sometimes animating, at others restraining, carried the development of the body in waves and tides to its flood.

Dr. d'Oelsnitz (Nice) contributed a paper on "Chronic Suprarenal Inadequacy in Infants." In the discussion which followed, Dr. Koplik (New York) said that he had been impressed by the associated disturbances of the viscera generally in abnormalities of the ductless glands. In the case of children the intestine was almost invariably disordered.

Prof. Swale Vincent thought that much more was being taught about internal secretion than was really known. The difficulties were enormous. Extirpation of the thyroid never produced myxedema. The pathology of myxedema or cretinism was something more than merely thyroid insufficiency.

Dr. Leonard Guthrie said that there was a distinction to be drawn between the obesity of Fröhlich's syndrome and that of hypernephroma. In the former the appearance was that of infantilism, in the latter that of fat adults.

A paper was also contributed by Dr. Fischer of New York on the treatment of septic cases of scarlet fever by neosalvarsan. He had treated ten apparently hopeless cases in this way, of which three recovered. He thought it was worthy of trial in cases in which nothing else could be done.

(To be continued)

9 *Cardiac Disease in Childhood, with Special Reference to Prognosis. C. H. Dunn, Boston.
10 *Diagnosis and Treatment of Pyelitis in Infancy. R. G. Freeman, New York.
11 *Analysis of One Thousand Cases of Epidemic Measles. C. V. Craster, Rosebank, N. Y.

4. **Pancreatic Insufficiency.**—From a clinical and bacteriologic study of three cases, Porter concludes that in the group of cases characterized by waste of most of the ingested fat, with or without loss of the ingested starches and proteins, we are probably dealing with a bacterial invasion of the pancreas secondary to the presence of an abnormal bacterial flora in the small intestine. To Porter the question of the value of vaccines in such a condition is brought up because in one case the results following the use of a vaccine were so striking that it seemed impossible that mere coincidence will explain them. It is not suggested that one certain organism is specific for this condition, although Porter regards it as quite reasonable that any pathogenic bacterium, or even the colon bacillus, under abnormal intestinal conditions, may become the inciter of a pancreatitis which may lead to a suppression or deficiency in one or the other of the pancreatic ferments.

5. **Status Thymolymphaticus.**—The four cases studied by the authors presented the same symptom-complex: pasty complexion, a flabby fat overgrowth, hypertrophied tonsils and adenoids, enlarged cervical, axillary, and inguinal lymph-nodes and signs of an enlarged thymus; all were bottle-fed and had the "pot belly" of the rachitic. Three of the four had a preliminary deafness. Three of the four had seizures of choking or attacks suggesting thymic asthma. All were apparently well nourished. In all no malady sufficient to cause death was noted clinically. In all cases death occurred before the arrival of a physician and under very similar circumstances. No other similar cases are known among the playmates or friends. All were of nervous temperament and became easily excited. One child had diphtheria in 1911 and was given 5,000 units of antitoxin, the other three children receiving at the same time 1,000 units each for prophylactic purposes. The post-mortem findings were practically identical in the four cases: the lymphoid hyperplasia and enlarged thymus prevailed in each. The weight of the thymi were, respectively, 42, 54, 25 and 40 gm. The histologic changes found in all of the cases are extremely suggestive of a chronic inflammation affecting principally the lymphatic tissues. Whether this chronic inflammatory reaction has been produced by poisonous substances formed in some other part of the body or eliminated by some unknown micro-organism affecting the lymphatic tissues, is difficult to say. The authors find it difficult to conceive that the enlargement of the thymus was the main causative factor in the deaths of the children.

8. **Mucous Cyst of Cecum.**—A child, aged 10 weeks, was first seen for continued vomiting. The infant had been nursed by its mother and had thriven well for the first two months of life. Then it began to vomit after taking nourishment. The physician who first saw it regarded the mother's milk as the cause of the trouble and advised artificial feeding. This was tried without benefit; the vomiting persisted and the nutrition failed rapidly. There was no pyrexia. The consultant recognized a sausage-shaped tumor in the lower right quadrant of the abdomen, 3 inches long by about 1 inch in diameter, freely movable, not tender; no muscular rigidity of abdominal walls. Distinct peristaltic waves were noticed traveling toward the site of the tumor. Shortly after entrance into the ward a high enema was given which brought away no flatus, and only a small amount of feces, in which there was no appearance of blood or much mucus. Following this the abdomen was immediately opened under spinal anesthesia. The oblong tumor mass was found to involve the lower portion of the ileum and cecum; above the mass the ileum was much distended, while below it the ascending colon was collapsed. Regarding it at first as an ileocecal intussusception, careful efforts were made at reduction, and when they failed, a resection was performed with end to end anastomosis, and the abdomen closed. On examination afterward of the incised mass its true nature was disclosed. Death occurred from peritonitis.

The pathologic report on the specimens removed at operation was as follows: "The tumor consists of the lower portion of the cecum with its contained cyst, and the appendix. The cyst, much collapsed, measures about 2 cm. in diameter, is unilocular, contains glairy mucoid material and is situated on the wall of the cecum opposite the ileocecal valve, extending over to and completely obstructing that orifice." Microscopic examination of the cyst walls showed the surface of the tumor projecting into the lumen of the cecum to be covered with mucous membrane similar to that of the intestine; the cyst to be lined with a somewhat stretched layer of columnar epithelium which, however, in some places was folded into gland formations. Beneath each surface of epithelium was a submucosa infiltrated with lymphocytes, and between these again are three more or less distinct layers of muscle. From this report the cyst was regarded as in all probability a retention cyst, arising either from some fault in development or from an inflammatory occlusion of the mouth of the original gland.

9. **Cardiac Disease in Childhood.**—The series of cases included in Dunn's investigation numbers 304 cases of cardiac disease. It throws a certain amount of light on the relative frequency of occurrence of the various etiologic factors. Rheumatic fever, 264 cases, 87 per cent.; congenital lesions, 21 cases, 7 per cent.; some recognized infection other than rheumatic fever, 9 cases, 3 per cent.; unknown etiology, 10 cases, 3 per cent. Acute infection, 206 cases, 78 per cent.; chronic endocarditis, 58 cases, 22 per cent.

Dunn points out that rheumatic fever is very much the commonest cause of cardiac disease in childhood. Cases with acute rheumatic infection localized in the heart are much commoner than patients suffering from chronic endocarditis.

Cardiac symptoms are due to two causes: first, acute infection localized in the heart; second, broken cardiac compensation. Of these two causes the first is the commoner. The liability of children to recurrent attacks of acute rheumatic infection, in any of which the heart may be involved, is very great. The immediate mortality of rheumatic cardiac disease is about 20 per cent. The subsequent mortality of patients with endocarditis of rheumatic origin, followed for at least ten years, is about 50 per cent. The final mortality of rheumatic fever followed for at least ten years is 60 per cent. The mortality is seen chiefly during childhood. The mortality after young adult life is reached falls to only 7 per cent.

The cause of death is heart failure. The cause of the heart failure may be either acute cardiac infection or broken compensation. In childhood the former cause is far the more common. After adult life is reached the latter cause is more common. The particular valvular lesion present has little or no relation either to the mortality or the amount of disability in adult life; except that aortic disease appears to be a particularly fatal lesion in childhood. The causes of the great mortality of rheumatic fever in children are: first, their greater liability to this infection; second, their greater liability to recurrent attacks; third, their greater liability to cardiac involvement. Patients who escape the dangers of childhood, and who enter adult life, are apt to show a remarkable freedom from disability. The majority of such patients can lead normal active lives. The probable cause of this freedom from disability lies in the fact that the cardiac damage occurs during the period of growth, and during this period a particularly perfect adaptation can take place between the heart and the patient, which enables the heart to meet the demands made on it. This adaptation is more perfect than can be attained in the adult. The earlier in life the cardiac lesion is acquired, the better is apt to be the result in adult life, as concerns ability to lead an active, normal existence; provided that the patient escapes the dangers of childhood. Treatment should be directed toward favoring the adaptation of child and heart. While guarding against overstrain, we must avoid too great limiting of the normal activities of childhood. In congenital cardiac disease, open ductus arteriosus is a favorable lesion.

10. **Diagnosis and Treatment of Pyelitis in Infancy.**—Pyelitis in infancy, due to the invasion of the pelvis of the kidney with colon bacteria resulting in a purulent inflammation, Freeman believes, can apparently occur with no perceptible rise of temperature at any time. These cases should be treated and cured by the means ordinarily used in pyelitis. The alkaline treatment of pyelitis, while it is safe and will control many cases, is markedly less efficient than other methods of treatment. Vaccines, either autogenous or commercial, are useful in controlling the constitutional symptoms of pyelitis. Hexamethylenamin, while sometimes effective in doses of from ½ to 2 grains several times a day, will not in these doses cure certain cases which may be controlled by very large doses.

Freeman urges that hexamethylenamin should always be administered in small doses first, but the dose should be rapidly run up, the child and its urine being carefully watched for symptoms of irritation of the kidneys.

Large doses of hexamethylenamin should not usually be continued for more than a week at a time, and then after several days without any treatment or with alkaline treatment it should be started at the maximum dose given before and the amount increased daily until an influence on the urine is obtained. Doses of 25 grains daily in a child of 6 months, and from 35 to 45 grains a day in a child from 9 to 12 months may be safely given in this way to some infants.

11. **Epidemic Measles.**—Of the 1,000 cases of measles studied by Craster the greatest number were in the month of June (186). The third year age period shows the greatest incidence of attack (195). The largest complication percentage, 81.3, and case mortality, 34.3 per cent., are found in the first year period. The seasonal prevalence of complication was highest in December, 78.6 per cent., and of case mortality in January, 25.2 per cent. The most frequent complication was otitis media, 495. The most common cause of death, bronchopneumonia and enteritis, 23.3 per cent. of total deaths. Average duration of the fever, four days. The onset of purulent otitis media on tenth or twelfth day may not be attended by unusual fever. If the temperature remains high after the fourth day, a possible grave complication is imminent. An initial high temperature does not necessarily point to a possible severe attack.

14. **Sodium Bicarbonate.**—Every infusion of sodium bicarbonate made by the authors caused a pronounced rise of blood-pressure following immediately on the start of the injection and being well sustained for varying periods. Hand in hand with the rise of pressure went an increase of amplitude of heart beat. This increase varied quantitatively as did the rise of pressure itself, its chief characteristic being its constancy. Not infrequently the amplitude of beat was doubled immediately after the injection of the bicarbonate, and the increased amplitude often persisted for half an hour or longer after the injection of the solution. In all of their fifty experiments with sodium bicarbonate they could not determine any effect on the rate of heart beat. When the bicarbonate was administered before shock was induced the rate of beat was not quickened, and when it was administered during the period of rapid heart action incidental to shock the rate was not slowed. In addition to its influence on the cardiovascular apparatus the sodium bicarbonate infusions exerted a marked effect on the respiratory function. The rate of respiration was sometimes increased, sometimes slowed, and sometimes unaffected.

These variations did not seem to depend on idiosyncrasies in the different dogs, for they observed all in the same dog following different injections of the same amount of the drug. The notable fact was that the depth of respiration was increased. The rise of pressure following the injections was not due to mere bulk of fluid. In a number of experiments a distinct rise was noted after the introduction of from 2 to 5 c.c. of a normal solution of sodium bicarbonate. In shock there is said to be an escape of plasma from the blood-vessels into the tissues. It has even been suggested that shock is due to increased specific gravity of the blood. It is possible that the introduction of a hypertonic solution might accomplish this purpose and that the sodium bicarbonate infusions might have been effective on this basis.

That this assumption is not correct, however, the authors proved by the simple experiment of infusing shocked dogs with the hypertonic salt solution and with hypertonic basic sodium phosphate solutions, with practically no effect on the low blood-pressure. Neither could alkalinity alone explain the rise in pressure. Sodium carbonate, for example, which is a much more strongly alkaline salt than is sodium bicarbonate, invariably gave a pronouncedly less marked rise of pressure. The basic sodic phosphate in most of the experiments gave no rise of pressure (this basic salt is in reality only slightly alkaline), and when a rise did occur following its use the authors were unable to determine positively that this rise was not coincidental rather than a casual result. The various solutions of sodic hydrate never caused a rise. The tribasic sodic phosphate, which is a strongly alkaline salt, caused only slight rise, and this rise was immediately followed by a fall that in two instances ushered in death.

The authors conclude that the pressor effect of sodium bicarbonate does not depend solely on the alkalinity of this salt. This conclusion is important in its bearing on the possible relationship between shock and acidosis. The possible blood-pressure raising effect of carbon-dioxid gas supplied directly to the blood in shock was also tested out. By properly regulating the flow of gas they could administer it over an indefinite period of time, and although the administration stimulated the respiratory function most actively it did not influence the rate of heart beat, amplitude of pulse pressure, or height of blood-pressure. When the carbon-dioxid gas was administered before shock was instituted it had no influence in warding off the oncoming fall of pressure, and when administered during shock it likewise had no influence in restoring pressure toward a normal level. It would seem to be clearly established therefore both that the pressor effect of sodium bicarbonate does not reside in the carbon dioxid radical, and that shock itself cannot be referred to acapnia. The direct vasomotor effect of the sodium bicarbonate solution on the blood-vessels was not tested out.

15. **Diagnosis of Chronic Appendicitis.**—Bassler describes the method of pinching the appendix as follows: If the patient is not too stout the lower border of the cecum is percussed from Poupart's ligament upward. Fortunately the cecum is usually distended with gas and an accurate level of the cecum when the patient is on the back can be determined. After this is noted, percussion transversely across the cecum is made to obtain its outer and inner edge. The outer edge is always possible of being noted. In percussing for this it is necessary when on the outer edge that the percussion stroke be directed straight backward toward the lateral edge of the body, and when on the inner, directly backward toward the junction of the psoas and iliacus muscles, at that area these lines being more oblique than the outer edge of the rectus. With an estimation of about where the appendix would be as judged from the location of the lower end and sides of the cecum, pressure on the abdomen should be made at that point.

When the cecum cannot be mapped out by percussion or the subject is well developed, and even in all, the second plan is to note the position of the right edge of the rectus muscle on the umbilical-spine line maintaining the site with a finger. Having the patient rise to a sitting position helps in palpating for the rectus edge. Standing at the right and facing the patient (for right-handed individuals) the thumb is placed vertical on the abdomen, the tip of the thumb pointing to the ensiform, when it is slowly pressed backward into the abdomen, not inward, outward, up or down. When the thumb has been sunk about half-way down to the back of the abdominal cavity, it is swung to the right of the patient at a right angle to the downward pressure line. This pinches the appendix against the iliacus muscle and unyielding structures under and at the side of it, and usually elicits pain or tenderness. It is well, having done this in the mid-distance between the anterior superior spine and the umbilicus and not having obtained tenderness, to move the thumb down about ½ inch, performing it again, and so on downward until one has reached almost to the brim of the pelvis. The same procedure on the left side serves as a control. By means of this method of downward and then right lateral pressure it is possible to elicit tenderness in the average case of chronic appendicitis. When tenderness is obtained on transverse pressure to the left it may be a Lane's kink, and when below it may be a tender ovary instead of an appendix.

16. **Effects of Extract of Hypophysis.**—Eighteen individuals were given the dried extract of the whole pituitary gland without other medication by Musser. The following effects were noted: Blood-pressure: Seventeen showed a rise in systolic blood-pressure, the greatest rise being 28 mm. of mercury. Usually a corresponding rise in diastolic pressure occurred, though rarely it remained at the same height as before taking the extract or even became lower. Pulse rate: The changes in the pulse rate were inconstant; an increase was generally observed, though in two individuals the rate was decidedly decreased. Diuresis: Six individuals noted a diuretic effect. The extent, absence, or presence of this symptom could not be accurately determined. The urine showed no particular change except in one case. Glycosuria was never observed. Intestinal tract: Diarrhea developed in seven cases, and four, previously costive, had daily movements during the period of taking the drug.

Subjective symptoms: Four individuals were apparently much benefited by the rise in pressure and general stimulative effect of the glandular extract on the unstriated muscle, and one person was benefited through the diuretic effect of the extract. In the remaining patients there was little effect noted except by those who developed the rather annoying diarrhea. Musser concludes therefore that prolonged administration of extracts of the pituitary gland exert a distinct pressor effect on the peripheral vascular apparatus, which persists for an appreciable time after discontinuation of the drug. This is apparently the only consistent effect following continued administration of the gland *per oram*; other results are variable and indefinite.

17. For description of this method which was introduced by White and Van Normal, see abstract, The Journal, Nov. 5, 1910, p. 1682.

18. **Influence of Foreign Bodies in Gall-Bladder.**—Experiments were undertaken by Pepper in the hope of finding some explanation for the gastric hyperacidity so frequently found clinically in association with cholelithiasis. Lichty's work on the same subject and covering the same ground appeared before the work was completed, thus rendering unnecessary their further prosecution. It seems worth while to Pepper, however, to report the results obtained in the first simple phase of the investigation, partly because they are not in general in accord with those of Lichty and partly because they control possible sources of error in his work. These are the use of the stomach-tube in feeding the animals, the administration of food at irregular intervals, and the brief postoperative period of observation. The essential feature of the experiment was to place in the gall-bladder with as little trauma as possible a more or less smooth sterile object, too large to enter the ducts, and after appropriate intervals to study the gastric secretion. The gastric analyses showed no changes as the result of the experimental procedure. In two animals the average acidity after operation was higher than before, while in the other two the reverse was true. In all the animals, both before and after operation, the averages for free hydrochloric acid lay between the figures 16 and 24.6.

20. **Etiology of Pernicious Anemia.**—Pilcher maintains that achlorhydria is merely a symptom denoting a marked degree of chronic gastritis. It is usually evoked through extra-gastric irritative factors which are in many instances capable of correction. There are, without exception, present in such stomachs great numbers of bacteria ordinarily considered pathogenic, among which streptococci are especially to be noted. Practically all recorded cases of authenticated pernicious anemia present the symptom of achlorhydria, and in his own series of thirty-four cases the presence of occult blood in the stomach extract. Thirty-four instances of pernicious anemia were noted in patients presenting the symptom of achlorhydria hemorrhagica gastrica. In a few of these cases the lack of hydrochloric acid and the presence of occult blood were known to be present at least one year before any blood-changes were to be noted. In others the phenomena of paresthesia were evidenced some time previous to blood impairment, and many had suffered for years from chronic gastrointestinal complaints. Eighty per cent. of cases of pernicious anemia have increased temperature some time during the course of the disease.

Pure cultures of streptococci have been found by competent observers in the blood of patients with pernicious anemia who were running a fever. Bacterial hemolysins are known to produce anemia resembling the pernicious type, as are other toxic substances, among which may be classed the lipoid group. Efforts directed to the control of bacterial growth in the body and particularly in the gastro-intestinal tract have caused complete remissions in this disease in some instances. The phenomena of occurrence, remission and reoccurrence of the blood-picture characteristic of pernicious anemia may be explained by our present knowledge of the action of toxins from whatever source, impairing the formation of antibodies until a bacteremia is produced which may be clinically recognized. The toxins present being eliminated by the profuse flora in the gastro-intestinal tract, the impairment of bodily resistance is accomplished through their absorption and the disturbance of digestion in cases of achlorhydria.

Finally, reactive and combative ability of patients suffering with achlorhydria varies in different patients, and on this ground alone might be explained the relatively rare occurrence of pernicious anemia, although the occurrence of achlorhydia is fairly common. Thus the development of pernicious anemia wound seem to be dependent on a personal idiosyncrasy of certain individuals; in fact, we must revert for the real etiologic factor of its inception to an embryonic tendency, the presence of which we are not as yet able to determine, until it has been stimulated into an active destructive agent of the blood by the toxins absorbed from the profuse bacterial flora present in the stomach.

23. **Epidemiology of Pellagra.**—The epidemiologic data presented in this report by Siler and Garrison are summarized as follows: 1. Pellagra shows a striking inequality of distribution in the ten townships within the county, the township rate of prevalence per 10,000 of population varying from 0 to 71. The city of Spartanburg, with a population of 17,517 gave a rate of 49 per 10,000 against 34 per 10,000 for the remainder of the county. Density of population while showing a tendency to conform to the relative prevalence of the disease does not alone offer an explanation of the geographic inequalities of its distribution within the county. The cotton-mill-village population gives a rate of prevalence of 104 per 10,000 against 19 per 10,000 for the remainder of the county, and against 16 per 10,000 for the rural sections alone. The variations in the rates of prevalence in the ten townships are in a measure proportional to the presence or absence of a large mill-village population. Excluding the mill-village population, there is still a marked discrepancy between the townships in the rural population alone, ranging from 0 to 29 cases per 10,000 of population. The excessive prevalence among the farming classes is found in the townships which have a relatively large mill-village population. The white population of the county gives a prevalence of 45 cases per 10,000; the negro population a prevalence of 9.5 per 10,000. Excluding the mill-village population which is practically all white, the remaining white population still gives a rate of prevalence (25.2 per 10,000) over two and a half times that among the negroes. The rate of prevalence per 10,000 for males in the county is 17; for females, 50.5 White males give a rate of 22.95 per 10,000; white females, 87.5 per 10,000; negro males, 3.9 per 10,000; negro females, 14.9 per 10,000. The rate of prevalence among children under 10 years of age and among adults aged 45 years and older is practically equal in the two sexes. The rate of prevalence drops among males between the ages of 19 and 45, whereas for females there is a remarkable excess of prevalence between these ages. In both males and females there is a striking fall in prevalence between the ages of 10 and 20 years.

The most significant fact with regard to occupation is the excessive prevalence of pellagra among women employed in housework. The excessive prevalence of pellagra in the mill-village population is found largely among women and children at home during the day. Among actual mill-workers the rate of prevalence between the two sexes appears to be about equal. One-half of the cases occurred singly in one family; about one-fourth occurred two in one family; the remaining fourth occurred in groups of three, four or five in one family.

The question of the possible relative importance of family relationship and household association is still under investigation. Among cases occurring singly in families, the proportion of children of both sexes under 10 years of age is low and that of adult females excessively high. Among cases occurring two or more in one family the proportion of young children is proportionately high, especially among males. While apparently authentic sporadic cases of pellagra within the county can be traced back to as early as 1894, the disease does not appear to have occurred in any great number of cases in any year until 1908. Since 1908 the incidence-rate appears to have rapidly increased each year to 1911. The number of new cases developing in 1911 appears to have been slightly greater than in 1912. There was no evidence pointing to any spring and fall recrudescence of the disease in the population so frequently referred to in the literature of pellagra. There is no particularly marked tendency for the seasonal recurrence to appear in an individual during the same month, year after year. Climatic conditions appear to influence the development of symptoms of the disease. If during the spring months precipitation is high, temperature low, and number of rainy days excessive, the appearance of acute symptoms, more particularly those involving the skin, is delayed.

It would appear that three or four years ago a large proportion of the cases observed in the county presented intestinal and nervous symptoms which were quite mild, and sometimes were confined almost exclusively to the cutaneous system, the disease appearing to be of a less virulent type in 1912 than in previous years. In the majority of cases (83 per cent.) economic conditions are poor and the disease is most prevalent among people of insufficient means. General health conditions in childhood do not appear to warrant consideration as etiologic factors when the disease develops in adult life. In a number of cases the development of pellagrous symptoms in children was preceded by one of the acute exanthematous diseases of childhood. About one-fourth of the cases gave a history of a preceding chronic disease in adult life.

In more than one-half of the cases (62 per cent.) most affected were married women (86 per cent.), and 86 per cent. of the married women had borne children. A history of illness immediately preceding the development of pellagra was elicited in 59 per cent. of the cases.

The most insanitary condition found in the county is the absence of properly constructed privies. Outside of a part of the city of Spartanburg which is supplied by a water-carriage sewage system, there is no effective provision in the county for the proper disposal of human excreta. A second striking unsanitary condition is the almost complete absence of effective screening of dwellings. These two conditions present a situation highly favorable to the transmission of disease organisms eliminated in the excreta, both by direct contamination of food and person and by insects. This situation is naturally aggravated in the mill-villages and small towns by the greater congestion of houses. The absence of effective screening for dwellings gives rise to conditions conducive to the possible transfer of diseases transmitted by biting insects.

Observations on the habitual use of the more common foodstuffs failed to discover any points of difference between pellagrins and non-pellagrins in the county or any facts which would seem to explain the strikingly greater prevalence of pellagra among certain classes of the population. The most striking defect in the general dietary of the working classes, appears to be the limited use of fresh meats, the animal protein being supplied largely in the form of cured meats, of which salt pork (especially bacon) is the most important. Unhygienic preparation of food appears to be a probable important factor in the general health of the population. Investigation of the kind, quantity, and quality of corn and corn products used in the county failed to bring to light any epidemiologic evidence pointing to the agency of corn as an etiologic factor in the disease. The presence of two cases in their series giving a definite history of no corn consumption within two years prior to the onset of symptoms, together with several other cases in which corn products were eaten, if at all, only in small quantity and at extremely rare intervals, would seem to argue strongly against any hypothesis that corn products alone are the causative agent of the disease.

31 *Rôle of Gastric and Intestinal Stasis in Some Cases of Epilepsy. H. Powers, Brooklyn, Mass.

31. Gastric and Intestinal Stasis in Epilepsy.—In the study of many cases of epilepsy in young children at the Children's Hospital, Powers came to believe that the gastro-intestinal disturbance preceded the epilepsy and was not merely a symptom. It must be admitted, he says, that the vast majority of individuals who suffer from stasis do not have epilepsy, but in his experience they do have headache, vertigo and other nervous symptoms caused by the toxemia that results from stasis. These symptoms of toxemia are of all shades of severity so that sometimes the diagnosis between these conditions and epilepsy is made with great difficulty and, it may be said, arbitrarily. Powers feels that in so-called "idiopathic" epilepsy the essential lesion is not in the nervous system. If it be true that epilepsy does not imply a defective central nervous system with a tendency to degeneration in the cells of the cortex and consequent mental deterioration, then the social status of the epileptic will have to be reconsidered. Laws designed to prevent the propagation of epileptics should then be so phrased as not to bar from marriage those in whom the disease is curable and probably not transmissible as such. A law barring from marriage the syphilitic, the alcoholic, the feebleminded and the insane would in effect bar those epileptics who ought not to be permitted to marry.

Finally, if it can be definitely established that the phenomenon known as "idiopathic," "inorganic" or "true" epilepsy is produced by a toxemia and that this toxemia is the result of stasis in the gastro-intestinal tract, the prognosis should be much better than it is at present, provided that the physician be equipped, not with drug therapy alone, but also with a knowledge of mechanical therapeutics, and that he use the bromids only as an adjunct to other treatment. A new exercise and a new method of self-massage for the treatment of stasis will be described in a subsequent paper.

54. **Inheritance of Epilepsy.**—In summarizing the facts which to him seem worthy of emphasis in a discussion of the inheritance of epilepsy Hecht urges that human society must concern itself more and more with the qualities in man that are physical and vital, as opposed to those that are mental and moral. In heredity we find the most potential factor in the evolutionary process of man. Environmental influences may modify but do not increase our original endowment. The essential thing in the preservation of the race is physical fitness, and inheritance, in its turn, is the essential and most to be desired thing in the development of such fitness. The methods with which we are to-day better able to explain the qualities and attributes inherited by man are perhaps those referred to as mendelian and biometric. It should, however, be thoroughly understood that no biologic phenomena, either in full or even in large part, meet the theoretic expectations of either method. The inheritance of epilepsy, however, is very worthy of being subjected to an analysis. Mendelian or biometric, in the hope that valuable data may be secured and in the end enable us to invoke the proper measures against the spread of the disease. The studies already made Hecht regards as highly instructive and suggestive, although there are many sources of error which to them seem almost impossible to overcome. Society has the moral right to interfere with the continuance of any human stock definitely known to be unalterably unsound and on the assumption that an overwhelming proportion of epileptics are of this type, the plan of segregation, efficiently and scientifically carried out, is a just one. The act of sterilization in the light of present knowledge is still open to criticism and objection and may, therefore, be considered premature and as a measure of legislative interference should not be endorsed. The mildly inferior epileptic constitutes a very great menace and one concerning which scientists are not prepared to make recommendation.

59. **Appendix Free in Abdominal Cavity without Suppurative Peritonitis.**—The appendix in Wagner's case was free of its cecal attachment, without any evidence of a purulent peritonitis, the exudative condition present being due to a carcinosis. The separation is explained by the pathologic condition in the appendix. The lumen was entirely occluded, probably involving the blood-vessels at the base to such an extent that sloughing was the natural sequence, the occluded lumen preventing infection of the peritoneal cavity. Omentum, bladder, rectum, intestines, and parietal peritoneum, all showed evidence of involvement.

61. **Sphygmomanometer of New Principle.**—Dearborn's sphygmomanometer consists merely of a properly adapted distal end-piece of an ordinary stethoscope firmly attached by a screw-thread to a spring-dynamometer with a transparent handle by means of which it may be grasped readily and pressed against the artery by the observer.

65. **Serologic Analyses in Neurology.**—As the result of his research Kaplan found that the Wassermann reaction is not present in the spinal fluid in all cases of syphilitic and parasyphilitic disease of the central nervous system. The use of increasing amounts of spinal fluid for the Wassermann test (*Auswertungs Methode* of Hauptmann) is a procedure capable of giving rise to non-specific inhibition in patients who did not come in contact with this disease. Serologically all nervous diseases are divided into two general and easily distinguishable classes, the negative and positive types. The negative type represents the non-luetic nervous diseases, the positive type the syphilitic and the parasyphilitic diseases. In the positive type group further differentiation is possible by serologic investigation in cases in which physical differentiation is difficult, such as between general paresis and cerebrospinal lues. Active and proper treatment markedly alters serologic pictures in many of the positive types. Such alteration may go on to any extent, even to the reduction to a complete negative picture. The greatest change to the negative occurs in cerebrospinal lues and the least in general paresis. In the cell-count in tabes may be found an index for or against treatment. Fully developed general paresis is best left untreated. Spinal cord compression from tumors or other causes shows a protein excess and an absence of pleocytosis.

66. **Respirator.**—The respirator devised by Tompkins is not cumbersome and heavy; in fact, it can be carried in a small case and weighs less than ten pounds. It does not depend on any brand of oxygen, nor does its operation depend on compressed gas. It is operated by hand and foot in the least tiring manner; both hand and foot can be changed without losing time or causing trouble. Its apparent initial cost is low, and it has no cost of upkeep. Finally, it makes use of air. If it is desired oxygen may be employed, or a combination of oxygen with a definite proportion of carbon dioxid, but Tompkins uses atmospheric air of which there is always a plentiful supply.

The technic is as follows: With the patient lying down, the shoulders are raised by means of a pad, so that the head falls well back. The mouth is opened and a prop or gag placed between the jaws. False teeth or other loose articles are removed from the mouth. Grasp the tongue and draw it, even strain it, well forward, pulling it as far as it will go. Pass the finger down the throat and swab out any mucus that may be present, and draw the epiglottis against the base of the tongue. The tongue, being held as well forward as possible, the mask is adapted to the face. With the tongue between the mask and the chin, and held firmly in place by a piece of gauze, strap the mask to the face; it must be very tight, so that no air may leak in or out. These details having been observed, the mask is connected to the valve mechanism by a piece of rubber tubing from eight to twelve inches long. The valve mechanism is connected by more tubing to a pump or bellows of some description. All connections being well made and tight, the bellows is pumped and air forced along the tubing through the valves into the lungs. By pressing down on the valve stem, the air in the lungs is forced out into the atmosphere by the elasticity of the lung tissue. The valve stem is allowed to rise, and air is again admitted to the lungs. The raising and lowering of the valve stem controls the number of respirations allowed per minute. On the valve mechanism is found a safety valve which controls the pressure of air. When the pressure of air in the lungs reaches a predetermined point, as set for on the index, this valve allows the excess air to pass into the atmosphere, and thus keep the pressure down to where it can do no harm. This is all there is to the machine.

2. **General Toxic Effect of Paints.**—The authors conclude from their experiments that there is no poisonous emanation from either basic lead carbonate or basic lead sulphate, even with much more thorough exposure than would occur to painters, or occupants of a freshly painted room, under ordinary conditions. The animals were exposed within a few inches of a freshly painted surface surrounding them on all four sides and roof as well. They believe that it may be taken that true lead poisoning when it does occur arises from swallowing, inhalation as dust followed by swallowing, or absorption from skin or an abraded surface, and not from volatile emanations.

3. **Influence of Copper on the Growth of Mouse Carcinoma.**—In one series of animals a solution of a cuprammonium sulphate was injected subcutaneously into tumor mice; in the second colloidal copper was employed. Cuprammonium sulphate ($CuSO_4.4NH_3.H_2O$) was obtained by adding to a saturated solution of $CuSO_4$ strong ammonia and then boiling; the blue crystals of the curprammonium salt, which separated out on cooling, were dissolved in 0 85 per cent. NaCl solution and used for injection, the concentration of the solution employed ranging from 0.62 per cent. to 0.70 per cent. of metallic copper. The lethal dose of this salt was found to be represented by about 0.05 gm. of copper per kilogram of body weight. The injections were made subcutaneously at a distance from the tumor. Only mice with small tumors were employed for experiment, and spontaneous retrogression of mouse tumor has been in experience an excessively rare event.

The results of the experiments made with the cuprammonium sulphate: The number of injections varied from two to five. The injections, which frequently caused inflammatory swelling, sometimes leading to necrosis of the skin at the site of injection, were always made as far as possible from the tumor so as to avoid any direct effect on the growth. In three cases complete disappearance of the tumor occurred, and in two other cases great diminution in size took place. In five experiments the tumor remained stationary for periods varying from five to ten days, and in the remaining two experiments an increase in size of the tumor attended with softening took place. With a view of avoiding the local inflammatory reaction which occurs when cuprammonium sulphate is used, it was determined to employ colloidal copper for subcutaneous injection. This was observed to be slowly absorbed without producing a marked irritating effect. Colloidal copper was prepared after Bredig's method, a galvanic current of 10 amperes being allowed to pass between two thick copper electrodes immersed in a beaker containing distilled water, free from CO_2, placed in a larger vessel filled with ice. In this way a colloidal solution of copper was obtained containing 0.04 to 0.3 per cent. of copper. It was found that the colloidal solution could be boiled without precipitation occurring, and when air was excluded no change in the aspect of the liquid occurred in the course of several days. In all the experiments made, however, the colloidal solution of copper was freshly prepared.

The addition of stains, such as methylene blue, eosin, and basic fuchsin, in small quantity, was found not to precipitate copper from solution. A solution of colloidal copper is incompatible with saline solutions. A very small quantity of sodium chlorid solution, for example, causes precipitation almost immediately. It was, therefore, used in a non-isotonic solution, the injections being slowly made into the subcutaneous fascia in amounts of about 1 c.c., in several areas removed as far as possible from the tumor in order to avoid a direct effect of the copper; in some cases intraperitoneal injections were employed (1 c.c.), or both methods of injection were used. The minimal lethal dose of colloidal copper was not determined. In all thirty-two experiments were made, the number of injections in individual mice ranging from two to seven. In these experiments it was found possible to keep the animals alive a much longer time than was the case when cuprammonium sulphate was employed. Nevertheless, the number of cases in which complete disappearance of the tumor was obtained was relatively less than in the preceding experiments. In the greater number of experiments in which an effect on the tumor was observed this was manifested by the tumor becoming stationary in growth.

The effect on the implanted tumor of injection of colloidal copper was much less pronounced than when cuprammonium sulphate was used. Some of the stationary tumors were kept under observation for a very much longer period of time than in the preceding experiments. In one case the tumor remained stationary for as long as three months. In four experiments repeated intravenous injections of colloidal copper were employed. The amount of fluid injected always exceeded 1 c.c. and in one case reached as much as 2 c.c. After the latter injection the mouse became collapsed with rapid and deep respiration, subsequently recovering and surviving for forty-two days. With this exception no ill effect followed on injection. After intravenous injection the implanted tumors increased slightly in size during the next few days, and then became soft, subsequently remaining stationary. On sectioning these tumors very marked degeneration was observed. The results obtained in this and the preceding section show that by means of injection of copper-containing fluids implanted tumors in a certain proportion of cases pass into a stationary condition or undergo regression, and suggest that a similar result might be obtained in cases of spontaneous carcinoma.

25. **Fatal Illness in Children Associated with Acute Interstitial Parotitis.**—Gordon's communication is the histologic observation of an unusual lesion—parotitis—in a series of four cases under observation in the postmortem room at St. Bartholomew's Hospital during the past few months. All of the patients in question were children. All had died after a short illness in which the symptoms pointed to meningo-encephalitis. Post-mortem meningeal congestion was found in all the cases, and in two of them there was flattening of the convolutions and other evidence of increased intracranial pressure. In all alike no pus was present in the meninges. There was no evidence of tubercle in the meninges, brain or elsewhere. The cerebrospinal fluid was clear and contained an excess of lymphocytes, but no visible bacteria. Sections of the cerebral cortex and of the cord failed on microscopic examination to yield histological evidence to justify a diagnosis of poliomyelitis.

As regards the rest of the body, the lymph-nodes both in the neck and mesentery were swollen. In two cases the lymphoid tissue in the small intestine was more prominent than usual, this change being most marked in Peyer's patches in one case, and in the solitary follicles in the other. In two of the cases petechial hemorrhages were seen; in the first in the parietal pleura and visceral pericardium, and in the second on the under surface of the liver and beneath the capsule of the kidneys. In all the children both heart's blood and cerebrospinal fluid failed to show growth on agar, and their illness would have remained a mystery had it not been for the following observation: Although the salivary glands were not obviously enlarged and had given rise to no symptoms, they were found in all the four children to show on histologic examination foci of acute inflammation—chiefly interstitial in distribution. The duration of their illness had varied. In one case the child died within twenty-four hours of the onset, and clinically it was a case of "convulsions." The others died on the second, third and twelfth day respectively. The illness from which these patients had suffered presented certain features of general similarity. In point of fact, as a result of the first two cases the last two had been suspected clinically of being instances of this disease. Three out of the four patients had drowsiness as a well marked initial symptom. All developed coma. One had delirium.

In all of the cases the eyes were sunken and fixed or staring, but not to one side; their axes were parallel—that is to say, there was no squint. In all the pupils were dilated. In none was any abnormality made out with regard to the disk. All of the cases presented the symptom of muscular rigidity in some form or other. In two the head was definitely retracted, and all had some stiffness of the neck muscles. Kernig's sign was positive in three. Three of the patients had twitching and two had "fits" of more or less general muscular rigidity, in course of which they died. Babinski was present in two cases, doubtful in one, and absent in one. Three of the patients lost their knee-jerks and the reflex from their abdominal muscles. The children had a marked pallor. All of the cases had pyrexia, and all had a frequent and feeble pulse. All of them had a certain amount of vomiting and diarrhea, the stools of three of them being of a greenish color. The cerebrospinal fluid was under increased pressure. On examination an increase was found in the cells, the number counted being 50,446, and 6,800, respectively, per cm. in three of the cases. In all the cases the predominant cells in the cerebrospinal fluid were lymphocytes. As regards the blood, the leukocyte count was 11,400. A differential count showed a well marked lymphocytosis.

26. **Ulcer of the Stomach in the Rat.**—The line of experiment that ultimately proved successful in Singer's work was very simple. Rats were placed in circular earthenware jars, ten animals in each jar. At the bottom of the jars were placed wood shavings contaminated by other rats, and throughout the experiment the shavings remained unchanged. The animals were fed only on wet bread. It was always found that in the course of a few hours the bread became contaminated with fecal matter, and in a few days was also overgrown with moulds. The majority of animals dealt with in this way were found to present more or less marked gastric changes of ulcerous nature when the treatment had been

continued for a fortnight or longer. In eighty rats thus treated for ten days or more ulcers were found in fifty-seven cases, or 71 per cent., while in 200 well-kept rats that were used as controls ulcers were encountered in only sixteen cases, or 8 per cent. Experiments were also made in feeding well-kept rats on bread mixed with stale feces and on bread that had become mouldy, but negative results had been obtained. In the case, however, of fourteen well-kept rats fed once on a mixture of bread and minced intestines of other rats ulcers were found after four weeks in ten cases, or 72 per cent. The actual causative factor remained in doubt. The condition of experiment suggests an infective agent of the nature of an organism normally present in some other part of the digestive tract.

31. **Tuberculin in Pulmonary Tuberculosis.**—The use of tuberculin in any form in the treatment of pulmonary tuberculosis, Fowler says, is not free from danger. Even with exceedingly small initial doses which are gradually increased the limit of tolerance may be suddenly reached and a reaction may occur. Its use is absolutely inadmissible in any case in which there is fever. Fever is the guide to the activity of the disease, therefore, the rôle of any remedial agent which can only be employed in afebrile cases is necessarily very limited. General reactions should be avoided. If one occurs the treatment should at once cease. To continue tuberculin injections with increasing doses in spite of reactions is unjustifiable and dangerous to the life of the patient. Focal reactions are also dangerous, as they cannot be controlled. They may also occur in the neighborhood of obsolete lesions, such as it is the object of all treatment to produce. Fowler has reported a case in which, under treatment with old tuberculin a patient expectorated four calcareous particles, one of which was surrounded by pigmented lung tissue, and also a small portion of lung tissue. Subsequently signs of excavation appeared at the apex of one lung. Calcareous particles are "sleeping dogs" which should not be disturbed. The treatment likely to be attended by the best results should follow the lines of rest and exercise originated by Dr. Otto Walther at Nordrach, and further developed by Dr. Marcus Paterson at the Frimley Sanatorium of the Brompton Hospital.

32. **Tuberculin in Treatment in Relation to Other Methods.**—White believes fully in tuberculin as an aid to treatment in tuberculous cases. He is himself a subject of tuberculosis and has for seven years taken tuberculin in some form or dose at least every two weeks, probably in all over 500 doses. It has done him no harm that he is conscious of. On the other hand he has been sure that it has done him great good when he has taken enough at one time to produce in his body a mild reaction. In small doses he has never been able to notice the slightest influence. White has now watched many patients who have taken tuberculin steadily for periods varying from two to five years—cases of tuberculosis of the eye, of bones, of glands, of skin and throat—and the improvement in many cases of them was due to tuberculin and to tuberculin mainly. However, the last dregs of the disease are always very hard to remove, and there is probably some other factor, he says, which we have not yet learned which must be added to tuberculin before we have a real specific for this disease.

33. **Tuberculin Treatment.**—Sahli is an ardent advocate of the tuberculin treatment and gives fifteen propositions in support of his position: All the various tuberculins are essentially identical. The apparent differences are dependent on the various degrees of admixed impurities. The active principle of all tuberculins is the protein of the tubercle bacilli. There is no proof of the existence of a tuberculin exotoxin. The fact that it is impossible to produce high sensibilization for tuberculin by previous tuberculin injection in healthy animals is no argument against tuberculin being actually the toxin of tuberculosis. The best tuberculins are those prepared from cultures as free as possible from adventitious albumins. To avoid disastrous mistakes in the therapeutic dosage it is advisable to provide the practitioner with tuberculin in suitably graduated dilutions. The use of tuberculin for diagnostic purposes ought to be condemned. It is unreliable both positively and negatively. Diagnostic injections are dangerous. The only diagnostic procedure Sahli advises is the cutaneous reaction with graduated dilutions. Its purpose is not diagnosis in the ordinary sense, but the determination of tuberculin sensibility in order to fix the proper initial dose for treatment. Tuberculin treatment is free from danger only if more obvious clinical reactions are avoided. In advanced cases tuberculin treatment may sometimes produce a certain symptomatic effect, but this effect does not compare with the utility of tuberculin in incipient cases.

In order that tuberculin treatment should be widely available for the most favorable incipient cases, it is indispensable that the general practitioner, and especially the family physician, should render himself proficient in tuberculin treatment. Correct tuberculin treatment is only possible if based on a solid and thorough knowledge of the action of tuberculin. The theory of the therapeutic action of tuberculin may now be regarded as well established. Tuberculin acts favorably only in cases where the human organism is not already sufficiently under the influence of absorbed tuberculin; that is, generally in slighter cases. It is not necessary to increase the doses of tuberculin to the furthest limit of tolerance. Many cases improved more with a much smaller dose. This optimum dose ought not to be overstepped. The large doses of tuberculin recommended recently for the purpose of reducing temperature have no curative action. Tuberculin has not the character of a true immunization, though it produces immunizatory effects in the organism. All localized tuberculosis is suitable for tuberculin treatment, provided that the patient's system is not already overloaded with tuberculin, and he is, therefore, too seriously ill. As a rule acute cases cannot be treated by tuberculin.

Tuberculin by means of multiple cuti-reactions after the method described by Sahli at the International Congress on Tuberculosis in Rome, 1912, has been proved harmless, and especially for incipient cases. It is based on the principle of enlarging the reactive surface. The strongest local (cutaneous) reaction is produced with the smallest amount of tuberculin. Well-diluted tuberculin treatment constitutes a real and great therapeutic progress.

46. **Percussion Sign of Typhoid Fever.**—This sign was described in The Journal, March 30, 1912, p. 979. Lesieur and Marchand now have a record of 150 cases in which the test for it has been applied. In eighteen the findings were negative and the cases proved to be not typhoid. In one case there was no localization of the typhoid in the intestines, the symptoms being meningeal and septicemic, but the percussion sign was positive and thus was the guide to the diagnosis, confirmed by the course of the case. The sign

is seldom positive in the later stages of the disease and it was never encountered in other infectious diseases. The reappearance or persistence of the sign after the temperature has returned to normal warns of impending relapse. The sign is an area of relative dulness on superficial percussion of the right base of the thorax. It is not to be found on the left side, and, if there are no lesions in the pleura or lungs to explain it, this dulness may be accepted as differentiating typhoid. They regard the dulness as the expression of the exaggerated antitoxic function of the liver in typhoid. No other infectious disease seems to affect the liver and the rest of the biliary apparatus to such an extent as typhoid.

49. **Pathogenesis and Treatment of Acute Articular Rheumatism.**—Weintraud presents arguments to sustain the assumption that the parenteral passage into the blood of bacterial proteins or of substances originating under the influence of the bacteria, create conditions of anaphylaxis. The parenteral penetration into the system of the bacterial proteins thus sensitizes the organism, and a special affinity of these proteins for the joints or the heart may lead to a special local sensitization. The specific reaction soon dies out, but new generations of bacteria repeat the process. Other bacteria may then get in their work as a complicating secondary infection. This conception of the origin of acute articular rheumatism throws light on the treatment, Weintraud continues. All the drugs which are known to be effectual in acute articular rheumatism are mild narcotics for the sensory functioning of the brain. It is certainly remarkable that the drugs with most effectual action are those which attenuate the sensory impulses from the joints. Some of them are actual anesthetics for the joints. We know that the outbreak of the symptoms accompanying the anaphylactic reaction in animals can be entirely prevented by general anesthetics (ether, ethyl chlorid, etc.). There is also much research on record which shows that the phenomena of inflammation, otherwise inevitable, do not occur if the sensory impulses from the region are attenuated or entirely suppressed.

50. **Gymnastic Exercises in Circulatory Disturbances.**—This address by E. Zander, Jr., was the principal one at the recent physiotherapy congress at Berlin. He declares that the method of therapeutic exercises, Swedish movements, etc., is of long tried efficiency, but that the theories with which its effects have been explained have been outgrown. A new theory must be built up; it must be based more on the biologic effect than the mechanical; more on the after-effect than on the action at the time; more on the effect on the periphery than on the center. In other words, the main task of therapeutic exercises is to draw on and train the muscles and the lungs in the task of compensation.

55. **Saphenofemoral Anastomosis in Treatment of Varices.**—Weichert has applied Delbet's technic slightly modified in five cases, in two on both sides. The results were less favorable than anticipated. All the patients were improved, but not to the hoped-for extent. The mediocre effects realized were out of all proportion to the severity of the operation.

56. **Test for Iodin in Urine.**—Ehrmann uses substances which practitioners are liable to have already on hand. About 2 c.c. urine are placed in a test-tube; 1 c.c. of dilute hydrochloric acid is poured into the tube and then 0.5 c.c. of commercial hydrogen dioxid (3 per cent.). The iodin released is shown up by addition of 1 c.c. toluol or 1 c.c. chloroform and the whole shaken up. A red layer of toluol floats on top, or there is a deep red layer of chloroform beneath.

57. **Serous Meningitis in the Puerperium Simulating Brain Tumor.**—Pelz reports the case of a young, otherwise healthy woman in an apparently normal puerperium, who suddenly developed headache, vertigo, vomiting, apathy and other signs of a brain tumor, the pulse 44, choked disk, the cerebrospinal fluid under high pressure, but no localizing symptoms. Then followed a stage of general convulsions, agraphia and apraxia, but improvement soon became manifest and the cure was complete in four or six weeks. Oppenheim reported a similar case with necropsy, and Nolen has published a case in which the same syndrome developed at the twelfth pregnancy and returned at the fourteenth and fifteenth, but the woman recovered. There can be no doubt of the connection between this periodically recurring, tumor-suggesting syndrome and the pregnancy or puerperium. The trouble is evidently a serous meningitis due to some intoxication connected with the pregnancy. We must not be too hasty to ascribe the recovery to decompressive operations in such cases. If an operation had been done in any of the above, the improvement would certainly have been attributed to it. A decompressive trephining was contemplated in Pelz' case but was constantly postponed. This patient had a history of intense headache, during her first childbed, coming on suddenly and persisting.

August 2, XLIII, No. 31, pp. 961-992

58 *Diagnosis of Perforated Gastric Ulcer; Six Cases. (Zur Diagnose des plötzlich in die freie Bauchhöhle perforierenden Magengeschwüres.) H. Ryser.

58. **Differential Diagnosis of Perforating Gastric Ulcer.**—Ryser's patients were three men of 22, 39 and 48 and three women of 46 to 63. The perforation was surrounded by indurated tissue, showing that the ulcer was of the callous type, boring deep, in all the cases. Sudden intense pain was the first symptom but there was actual collapse only in two of the cases. In most cases the pain and tenderness are at the seat of the perforation but other patients refer the pain to the ileocecal region, misleading the physician to assume appendicitis. This occurs when considerable stomach content has escaped through the perforation and has spread downward. Vomiting seldom occurs as the vomiting movements of the stomach force the contents through the perforation instead of up to the mouth. The physician finds the patient generally in bed, lying motionless on his back, in great distress from the pain. The face is pale and covered with cold sweat. Later, patches of red may be seen in the face and the extremities are cyanotic, showing that the organism is suffering severely from the intoxication. In two of his cases the pulse kept good and strong for several hours; in the others it grew fast and small at once. The temperature may be normal or above or below. The breathing is rapid and shallow. In one case hiccough came on in a few hours. A history of gastric trouble suggesting ulcer is a great aid in differentiating, as also the boat-shaped retraction and rigidity of the abdominal wall. If only a small amount of stomach content escapes the abdominal wall may not grow rigid, but in his cases the rigidity was pronounced or could be elicited by light pressure on the abdomen. The liver dulness was normal in three cases, much reduced in one case, normal at first but absent

an hour later in another, and in the sixth there was no area of dulness over the liver. A perforating appendix never causes such intense pain from the start, and the rigidity is more apt to be restricted to that half of the abdomen. A ruptured pyosalpinx in another case simulated the picture of a perforated gastric ulcer, especially as the young woman had long suffered from dyspepsia and had even taken a course of treatment for gastric ulcer, while there was no history of gynecologic trouble. The operation revealed the stomach intact.

July 24, XXXIX, No. 30, pp. 1441-1488

59 Combined Treatment of Syphilis. (Ueber die Heilung der Syphilis durch die kombinierte Salvarsan-Quecksilberbehandlung.) W. Scholtz and E. Riebes.
60 Psoriasis is a Clinical Entity. (Ist die Psoriasis ein Symptom chronischer Infektionskrankheiten—Tuberkulose, Syphilis?) W. Schoenfeld.
61 *Serotherapy of Skin Diseases. (Ueber Serumbehandlung von Hautkrankheiten.) G. Stümpke.
62 *Artificial Light in Treatment of Surgical Tuberculosis. R. Hagemann.
63 Perception of Light and of Colors. (*Vergleichende Untersuchungen über den Licht- und Farbensinn.*) F. W. Fröhlich.
64 *Influence of Experimental Thymectomy on Growth. (Ueber die Thymusdrüse.) K. Basch.
65 Pathology of the Knee. F. Bähr.
66 *Pyelitis and Otitis Media in Infants. F. Glaser and H. Fliess.
67 Rhinoliths. (Zwei bemerkenswerte Fälle von Nasensteinen.) O. Heinemann.

61. **Serotherapy of Skin Diseases.**—Stümpke has been applying transfusion of serum or whole blood in quite a number of cases and obtained very favorable results in itching eczema, in lichen ruber planus and herpes gestationis and in urticaria, while the results were sometimes good and sometimes negative in parasitic eczema, pemphigus and psoriasis. Some of the cases had proved refractory to all other measures. The favorable effect was realized only in the skin affections with a general cause and not of purely local origin. As a rule, he injected on an average 20 or 25 c.c. of serum after defibrination and centrifugation of the blood, repeating the infusion two or three times at intervals of from three to five days.

62. **Artificial Light in Treatment of Surgical Tuberculosis.**—Hagemann's article issues from König's clinic at Marburg and a communication from König, himself, was recently summarized in these columns July 26, 1913, p. 314, bearing on the same subject, namely, the fine results obtained with the mercury quartz lamp, exposing the whole body as in Rollier's method of utilizing the direct sunshine in the Swiss mountains. Hagemann emphasizes that the results with this artificial sunlight are so good and the method is so cheap and easily applied anywhere, without the necessity for long sojourns away from home, it permits the poorest to have the advantage of the therapeutic application of the chemical rays.

64. **The Thymus Gland.**—The untimely death of Karl Basch put an end to the important researches of which this is his last report. It is illustrated and shows the great difference in development between puppies of the same litter when the thymus was removed from some of them. The results demonstrate further that the thymus is involved not only in the growth of the bones and the eyes and in the excitability of the nervous system, but that it has some close connection with the lymph system.

66. **Otitis Media and Pyelitis in Infants.**—Glaser and Fliess have encountered three cases which have convinced them that otitis media is extremely liable to accompany pyelitis or precede it, and should be suspected even when there are no manifest signs of ear trouble whenever the fever keeps high. In one case the colon-bacillus pyelitis was evidently a complication permitted by the general debility resulting from the unsuspected otitis media; the child recovered its health after paracentesis and the cure of the otitis. They reiterate that when an infant has fever although it seems to be explained by discovery of pyelitis, yet the greatest attention should be paid to the ear. Otitis media may be the primary trouble even although there are no signs of it to be detected, no bulging of the drum, no redness and no tenderness in the mastoid. If the membrane shows any signs of redness they urge to incise it at once. The pyelitis in such cases is merely secondary, the result of mixed infection.

77 Radiology of the Stomach. (Neuere Ergebnisse der Radiologie des Magens.) Hurter.

68. **Sweating Procedures in Internal Diseases.**—Schwenkenbecher concludes his remarks on this subject with the statement that the systematic use of hot water baths may prove a great help in various diseases. The baths can be modified as to the amount of water, the temperature and the duration of the bath so as to adapt them to a delicate constitution and a weakened circulatory system. In kidney disease the sweating procedure diverts the fluid from the edema to the skin, and thus benefits, but the assumption that large amounts of nitrogen and chlorids can be eliminated in the sweat is not justified by the facts. Although a little more is thus eliminated in the sweat of nephritics than of healthy persons, yet the total is comparatively small. Even an energetic sweating bath cannot wash out more than 1 gm. of nitrogen and 2 gm. of sodium chlorid in this way, and in the individual case the question must be thoroughly studied whether this compensates for the demands made on the system by the sweating procedure. Hot local baths, hot baths for the feet or hot packs for the trunk in case of uremic headache and nausea, often have a marked influence on the symptoms of nephritis. But even with these it is of the utmost importance, as with all sweating procedures, to see that enough fluid is ingested or supplied in some way to take the place of that lost in the sweat. It may be wise also to place a cooling appliance on the heart. He says that bacteria can pass from the blood into the sweat, but that this occurs extremely rarely. He thinks that in syphilis sweating procedures are not applied as often as they should be for the tertiary, torpid syphilids of the skin and mucous membranes, and torpid bone lesions. Baths facilitate the mercurial inunctions. On the other hand, he warns emphatically against sweating procedures in syphilitic nervous affections, as they are liable to aggravate them. He remarks that in applying heat or hot baths in treatment of chronic arthritis the intensity of the heat applied is an important factor in the results; the action is more rapid and more intense the hotter the bath. Baelz has called attention to the fact that certain thermal springs with a temperature of 54 C. are the most effectual of all in Japan in the treatment of chronic joint disease.

70. **Anesthetic for Delivery.**—Fuchs relates a number of experiences which sustain his general conclusion that up to the present no means is known of rendering delivery painless which is not fraught with some danger. He says of the scopolamin "twilight sleep" that it is so dangerous for the respiration center of the fetus that he has abandoned it entirely. In his service one otherwise normal child succumbed evidently to the "scopolamin trauma" alone, and three others were born with lagophthalmos, cyanosis, sluggish pupils and very slow respiration, but these three children finally threw off the effect of the drug after a week of som-

nolency, taking scarcely any nourishment. He cites a case to show the medicolegal complications possible when a woman is delivered during the "twilight sleep": When the woman returned to full consciousness and found twins beside her, she refused to accept the two infants as her offspring. The accusation of changing the children while the mother is unaware of what is going on is also within the possibilities.

71. Onset of Multiple Sclerosis with Visual Disturbances.—Auerbach and Brandt call attention to their experience with a group of fourteen cases in which the first signs of anything wrong were visual disturbances, headache and dizziness. Although vision was much reduced, the ophthalmoscope revealed little if anything abnormal, and the visual disturbances gradually subsided. In 80 per cent. of the cases only one eye was affected. Moving the eyeball around and pressure on it elicited pain. The periphery of the field of vision was not altered but there was almost absolute scotoma for red and green and relative for white. The diagnosis was retrobulbar neuritis, and under mild inunctions and sweating procedures vision returned to normal in three or four weeks in the majority. In about 12 per cent. of the cases optic atrophy developed and the papilla was blanched even in the cases with good functional outcome. Neurologic examination revealed in nearly every instance symptoms suggesting incipient multiple sclerosis, including nystagmus, intention tremor and modification of the reflexes, but no tendency to scanning speech, tenesmus or disturbance in the gait. Fleischer has reported that among forty-two cases of retrobulbar neuritis. this proved in 66 per cent. to be the first symptom to attract attention to oncoming multiple sclerosis. This was the case in 45 per cent. of the thirty-seven cases of retrobulbar neuritis reported here. Some of the patients were kept under supervision and there was an interval of years, up to fifteen years, before the multiple sclerosis induced very serious symptoms. In many instances three to six years afterward the patients were still able to attend to business. The cases commencing with visual disturbances seem to have an unusually protracted course. Auerbach and Brandt add that a recent letter from Miura of Japan confirms the rarity of multiple sclerosis in Japan. Miura has never encountered it in the thousands of necropsies at his institute. They state further that they have been told that the western coast of America seems also to be free from it; in any event, it is far less common in America than in Europe.

75. Salt Solution as a Purgative.—Best reviews his experiences with some dogs with Pawlow fistulas. The results also show, he says, that physiologic salt solution passes through the gastro-intestinal tract without irritating it or interfering with osmotic conditions, while there is nothing he knows of which is passed along so rapidly. His clinical experience confirms these experimental findings. He had patients drink two glassfuls of a 0.9 per cent. solution of sodium chlorid, twenty minutes before breakfast. After nine or twelve minutes defecation followed. The stomach expels the salt solution remarkably promptly, setting up peristalsis throughout the intestinal tract. In the dogs 1 liter of the salt solution passed entirely through the alimentary tract and was expelled in thirty minutes, unless the animals were thirsty; in this case part of the fluid was absorbed. The larger the amount ingested the more rapid the passage. Most mineral waters are hypertonic and are absorbed in the duodenum unless large quantities are taken. The accumulation of the fluid in the lower bowel has a purgative influence and this is supplemented by the peristalsis reflex emanating from the stomach. After drinking the salt solution on an empty stomach in the morning he has the patient follow it with a cup of coffee or other appetizing drink. With atony of the stomach, the rapid expulsion of the physiologic salt solution makes it the only regulator of the bowels to use, he declares.

78-80. Abderhalden Serodiagnosis in Infectious Disease, Etc.—Abderhalden and Andryewsky report experiences which suggest the possibility of diagnosing infectious diseases by means of the optic and dialysis biologic method, possibly also determining the special organs involved. The question is now to learn whether the defensive ferments involved are an aid or detriment to the organism. They possibly may be instructive for the prognosis. Their presence indicates at least that the organism is defending itself. The response to the test after injection of tuberculin may prove especially important in testing cattle. This communication deals principally with the application of the test to bovine tuberculosis. A negative response was constantly obtained in healthy animals (50), positive in fifteen experiments after injection of a suspension of killed tubercle bacilli, as also in eight cases in which healthy animals had developed experimental tuberculosis.

Gambaroff reports from Moscow forty-eight cases of cancer and thirty-seven other cases in which the Abderhalden technic was applied, including twenty-two pregnant women and ten normal persons. The tabulated details show remarkable concordance, constantly negative responses in the normal serum and constantly positive in all the others, with the single exception of a syphilitic who gave a positive cancer reaction.

81. Ileus and Appendicitis.—Wiegels reports nine cases in which the ileus developed in consequence of appendicitis although in some of the cases the interval since had been many years, up to seventeen in one instance.

82. Seasickness and Vagotony.—The condition of atony of the vagus nervous system, called "vagotony" by Eppinger and Hess, was mentioned in The Journal August 16, 1913, p. 520, abstract 80. Fischer calls attention to the remarkable similarity or identity of the symptoms of seasickness with those of typical vagotony, and urges treatment of seasickness on the principles which have been found effectual in treatment of vagotony, that is to say, injection of atropin. He describes extensive experiences on a stormy passage across the Atlantic last winter. He found that persons with the signs of vagotony were more liable to develop seasickness than others. In fifty-two severe cases of seasickness he gave a subcutaneous injection of atropin in a dose of 0.001 gm. to men and 0.00075 gm. to women. All the symptoms of seasickness had generally disappeared by the end of three or four hours, only in very exceptional cases was a second injection necessary. In one group of eight very seasick persons given the injection, all felt entirely well the next morning except two who were only much improved, while a similar group not given any treatment had their seasickness continue unmodified. The harmlessness of the atropin in this dose, he says, is beyond question. By the mouth a good effect was apparent in thirty cases, but it was less pronounced and slower in developing. The dose by the mouth was twenty drops of a 1 per thousand solution. He explains how nearly all the symptoms of seasickness can be traced to irritation of the vegetative nervous system, and this he ascribes to the movements of the boat.

83. This is the same article as the one reviewed in Abstract 138 below.

85. **By-Effects of Hexamethylenamin.**—Cuntz warns that this drug (urotropin) cannot be regarded as absolutely harmless. With the usual dosage he has witnessed hematuria and albuminuria develop in two cases. In the first the bladder was evidently seriously irritated; in the second case albuminuria, leukocytes and epithelial cells were found in the urine after administration of hexamethylenamin, subsiding on suspension of the drug and returning on its resumption.

Petersburger medizinische Zeitschrift

July 28, XXXVIII, No. 14, pp. 163-174

91 *Febrile Abortion. (Bericht über 593 Aborte mit spezieller Berücksichtigung der Therapie des fieberhaften Aborts.) A. Waeber.
92 *Uterine Cancer in the Riga District. (Zur Statistik des Karzinoma uteri.) B. Herzfeld.

91. **Treatment of Abortion.**—Waeber states that in 90.4 per cent. of the 593 cases of abortion reported the women had normal temperature throughout, while 9.6 per cent. had fever after evacuation of the uterus. The total mortality was 0.67 per cent., but in only one case was the fatality due to infection from the genital organs and in this case the abortion had been induced by the woman herself with a nail. He makes a practice of clearing out the uterus at once, and all the patients in the uncomplicated cases recovered. He says that bacteriologic findings are of no moment, for almost any of the germs in the vagina are liable to become virulent under favoring conditions, and that there are only two signs of unusual virulence which can be depended on, namely, when one of the germs crowds out all the others in the cultures, and when the germs in the blood proliferate so rapidly that the blood looks as it if were laked.

92. **Cancer of the Uterus.**—Herzfeld states that in ten years at the dispensary connected with the city hospital at Riga (Russia) the uterine cancers formed 1.9 per cent. of the 7.947 cancer cases in women and the operability was 37.2 per cent. up to 1909. Since that date it has been over 47 per cent., showing that the systematic campaign of education then started is beginning to have some effect. In addition to the above, there were 195 with uterine cancer among the 3.939 cancer cases admitted to the hospital. Of the total material, 4.2 per cent. were in women between 20 and 30; 8.9 per cent. between 60 and 70, and 2.1 per cent. between 70 and 80. Most of the women had borne four or five children, but in 8.7 per cent. the women were nulliparae or virgins. The latter group includes two women under 30. In the inoperable cases the first signs of trouble had been noticed two weeks up to a year before in the majority, but in four cases the interval had been from two to ten years.
